19.4 Flat RAMBO phase space

This module implements the flat `RAMBO` phase space for massless and massive particles using the minimal d.o.f $3n - 4$ in a straightforward parameterization with a single channel. We generate n mass systems M_i with $M_0 = \sqrt{s}$ and $M_n = 0$. We let each mass system decay $1 \rightarrow 2$ in a four-momentum conserving way. The four-momenta of the two particles are generated back-to-back where we map the d.o.f. to energy, azimuthal and polar angle. The particle momenta are then boosted to CMS by an appriopriate boost using the kinematics of the parent mass system.

19.5 Resonance Handler

For various purposes (e.g., shower histories), we should extract the set of resonances and resonant channels from a phase-space tree set. A few methods do kinematics calculations specifically for those resonance data.

⟨resonances.f90⟩≡
  ⟨*File header*⟩

  module resonances

  ⟨*Use kinds*⟩
  ⟨*Use strings*⟩
  ⟨*Use debug*⟩
    use string_utils, only: str
    use format_utils, only: write_indent
    use io_units
    use diagnostics
    use lorentz
    use constants, only: one
    use model_data, only: model_data_t
    use flavors, only: flavor_t

  ⟨*Standard module head*⟩

  ⟨*Resonances: public*⟩

  ⟨*Resonances: parameters*⟩

  ⟨*Resonances: types*⟩

  contains

  ⟨*Resonances: procedures*⟩

  end module resonances

19.5.1 Decay products (contributors)

This stores the indices of the particles that contribute to a resonance, i.e., the decay products.

⟨*Resonances: public*⟩≡
    public :: resonance_contributors_t

⟨*Resonances: types*⟩≡
    type :: resonance_contributors_t
       integer, dimension(:), allocatable :: c
     contains
     ⟨*Resonances: resonance contributors: TBP*⟩
    end type resonance_contributors_t

Equality (comparison)

⟨*Resonances: resonance contributors: TBP*⟩≡
    procedure, private :: resonance_contributors_equal

2232

```
      generic :: operator(==) => resonance_contributors_equal
```

⟨*Resonances: procedures*⟩≡
```
    elemental function resonance_contributors_equal (c1, c2) result (equal)
      logical :: equal
      class(resonance_contributors_t), intent(in) :: c1, c2
      equal = allocated (c1%c) .and. allocated (c2%c)
      if (equal) equal = size (c1%c) == size (c2%c)
      if (equal) equal = all (c1%c == c2%c)
    end function resonance_contributors_equal
```

Assignment

⟨*Resonances: resonance contributors: TBP*⟩+≡

         contributors_out%c = contributors_in%c
      end if
    end subroutine resonance_contributors_assign
```

19.5.2 Resonance info object

This data structure augments the set of resonance contributors by a flavor object, such that we can perform calculations that take into account the particle properties, including mass and width.

Avoiding nameclash with similar but different `resonance_t` of `phs_base`:

⟨*Resonances: public*⟩+≡
```
    public :: resonance_info_t
```

⟨*Resonances: types*⟩+≡
```
    type :: resonance_info_t
      type(flavor_t) :: flavor
      type(resonance_contributors_t) :: contributors
    contains
     ⟨Resonances: resonance info: TBP⟩
    end type resonance_info_t
```

⟨*Resonances: resonance info: TBP*⟩≡
```
    procedure :: copy => resonance_info_copy
```

⟨*Resonances: procedures*⟩+≡
```
    subroutine resonance_info_copy (resonance_in, resonance_out)
      class(resonance_info_t), intent(in) :: resonance_in
      type(resonance_info_t), intent(out) :: resonance_out
      resonance_out%flavor = resonance_in%flavor
      if (allocated (resonance_in%contributors%c)) then
```

```
            associate (c => resonance_in%contributors%c)
               allocate (resonance_out%contributors%c (size (c)))
               resonance_out%contributors%c = c
            end associate
         end if
      end subroutine resonance_info_copy
```

⟨*Resonances: resonance info: TBP*⟩+≡
```
    procedure :: write => resonance_info_write
```

⟨*Resonances: procedures*⟩+≡
```
    subroutine resonance_info_write (resonance, unit, verbose)
      class(resonance_info_t), intent(in) :: resonance
      integer, optional, intent(in) :: unit
      logical, optional, intent(in) :: verbose
      integer :: u, i
      logical :: verb
      u = given_output_unit (unit);  if (u < 0)  return
      verb = .true.;  if (present (verbose))  verb = verbose
      if (verb) then
         write (u, '(A)', advance='no') "Resonance contributors: "
      else
         write (u, '(1x)', advance="no")
      end if
      if (allocated (resonance%contributors%c)) then
         do i = 1, size(resonance%contributors%c)
            write (u, '(I0,1X)', advance='no') resonance%contributors%c(i)
         end do
      else if (verb) then
         write (u, "(A)", advance="no")  "[not allocated]"
      end if
      if (resonance%flavor%is_defined ()) call resonance%flavor%write (u)
      write (u, '(A)')
    end subroutine resonance_info_write
```

Create a resonance-info object. The particle info may be available in term of a flavor object or as a PDG code; in the latter case we have to require a model data object that provides mass and width information.

⟨*Resonances: resonance info: TBP*⟩+≡
```
    procedure, private :: resonance_info_init_pdg
    procedure, private :: resonance_info_init_flv
    generic :: init => resonance_info_init_pdg, resonance_info_init_flv
```

⟨*Resonances: procedures*⟩+≡
```
    subroutine resonance_info_init_pdg (resonance, mom_id, pdg, model, n_out)
      class(resonance_info_t), intent(out) :: resonance
      integer, intent(in) :: mom_id
      integer, intent(in) :: pdg, n_out
      class(model_data_t), intent(in), target :: model
      type(flavor_t) :: flv
      if (debug_on) call msg_debug (D_PHASESPACE, "resonance_info_init_pdg")
      call flv%init (pdg, model)
      call resonance%init (mom_id, flv, n_out)
    end subroutine resonance_info_init_pdg
```

```
subroutine resonance_info_init_flv (resonance, mom_id, flv, n_out)
  class(resonance_info_t), intent(out) :: resonance
  integer, intent(in) :: mom_id
  type(flavor_t), intent(in) :: flv
  integer, intent(in) :: n_out

  logical, dimension(n_out) :: contrib
  integer, dimension(n_out) :: tmp
  if (debug_on) call msg_debug (D_PHASESPACE, "resonance_info_init_flv")
  resonance%flavor = flv
  do i = 1, n_out
     tmp(i) = i
  end do
  contrib = btest (mom_id, tmp - 1)
  allocate (resonance%contributors%c (count (contrib)))
  resonance%contributors%c = pack (tmp, contrib)
end subroutine resonance_info_init_flv
```

⟨*Resonances: resonance info: TBP*⟩+≡
```
    procedure, private :: resonance_info_equal
    generic :: operator(==) => resonance_info_equal
```

⟨*Resonances: procedures*⟩+≡
```
    elemental function resonance_info_equal (r1, r2) result (equal)
      logical :: equal
      class(resonance_info_t), intent(in) :: r1, r2
      equal = r1%flavor == r2%flavor .and. r1%contributors == r2%contributors
    end function resonance_info_equal
```

With each resonance region we associate a Breit-Wigner function

$$P = \frac{M_{res}^4}{(s - M_{res}^2)^2 + \Gamma_{res}^2 M_{res}^2},$$

where s denotes the invariant mass of the outgoing momenta originating from this resonance. Note that the M_{res}^4 in the nominator makes the mapping a dimensionless quantity.

⟨*Resonances: resonance info: TBP*⟩+≡
```
    procedure :: mapping => resonance_info_mapping
```

⟨*Resonances: procedures*⟩+≡
```

19.5.3 Resonance history object

This data structure stores a set of resonances, i.e., the resonances that appear in a particular Feynman graph or, in the context of phase space, phase space diagram.

⟨*Resonances: public*⟩+≡
```
    public :: resonance_history_t
```

⟨*Resonances: types*⟩+≡
```
    type :: resonance_history_t
       type(resonance_info_t), dimension(:), allocatable :: resonances
       integer :: n_resonances = 0
    contains
     ⟨Resonances: resonance history: TBP⟩
    end type resonance_history_t
```

Clear the resonance history. Assuming that there are no pointer-allocated parts, a straightforward `intent(out)` will do.

⟨*Resonances: resonance history: TBP*⟩≡
```
    procedure :: clear => resonance_history_clear
```

⟨*Resonances: procedures*⟩+≡
```
    subroutine resonance_history_clear (res_hist)
      class(resonance_history_t), intent(out) :: res_hist
    end subroutine resonance_history_clear
```

⟨*Resonances: resonance history: TBP*⟩+≡
```
    procedure :: copy => resonance_history_copy
```
⟨*Resonances: procedures*⟩+≡
```
    subroutine resonance_history_copy (res_hist_in, res_hist_out)
      class(resonance_history_t), intent(in) :: res_hist_in
      type(resonance_history_t), intent(out) :: res_hist_out
      integer :: i
      res_hist_out%n_resonances = res_hist_in%n_resonances
      allocate (res_hist_out%resonances (size (res_hist_in%resonances)))
      do i = 1, size (res_hist_in%resonances)
         call res_hist_in%resonances(i)%copy (res_hist_out%resonances(i))
      end do
    end subroutine resonance_history_copy
```

⟨*Resonances: resonance history: TBP*⟩+≡
```
    procedure :: write => resonance_history_write
```
⟨*Resonances: procedures*⟩+≡
```
    subroutine resonance_history_write (res_hist, unit, verbose, indent)
      class(resonance_history_t), intent(in) :: res_hist
      integer, optional, intent(in) :: unit
      logical, optional, intent(in) :: verbose
      integer, optional, intent(in) :: indent
      integer :: u, i
      u = given_output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write(u, '(A,I0,A)') "Resonance history with ", &
           res_hist%n_resonances, " resonances:"
      do i = 1, res_hist%n_resonances
         call write_indent (u, indent)
         write (u, "(2x)", advance="no")
         call res_hist%resonances(i)%write (u, verbose)
      end do
    end subroutine resonance_history_write
```

Assignment. Indirectly calls type-bound assignment for the contributors.

Strictly speaking, this is redundant. But NAGfor 6.208 intrinsic assignment crashes under certain conditions.

⟨*Resonances: resonance history: TBP*⟩+≡
```
    procedure, private :: resonance_history_assign
    generic :: assignment(=) => resonance_history_assign

      end do
    end function resonance_history_has_flavor
```

19.5.4 Kinematics

Evaluate the distance from a resonance. The distance is given by $|p^2 - m^2|/(m\Gamma)$. For $\Gamma \ll m$, this is the relative distance from the resonance peak in units of the half-width.

⟨*Resonances: resonance info: TBP*⟩+≡
```
    procedure :: evaluate_distance => resonance_info_evaluate_distance
```

⟨*Resonances: procedures*⟩+≡
```
    subroutine resonance_info_evaluate_distance (res_info, p, dist)
      class(resonance_info_t), intent(in) :: res_info
      type(vector4_t), dimension(:), intent(in) :: p
      real(default), intent(out) :: dist
      real(default) :: m, w
      type(vector4_t) :: q
      m = res_info%flavor%get_mass ()
      w = res_info%flavor%get_width ()
      q = sum (p(res_info%contributors%c))
      dist = abs (q**2 - m**2) / (m * w)
    end subroutine resonance_info_evaluate_distance
```

Evaluate the array of distances from a resonance history. We assume that the array has been allocated with correct size, namely the number of resonances in this history.

⟨*Resonances: resonance history: TBP*⟩+≡
```
    procedure :: evaluate_distances => resonance_history_evaluate_distances
```

⟨*Resonances: procedures*⟩+≡
```
    subroutine resonance_history_evaluate_distances (res_hist, p, dist)
      class(resonance_history_t), intent(in) :: res_hist
      type(vector4_t), dimension(:), intent(in) :: p
      real(default), dimension(:), intent(out) :: dist
      integer :: i
      do i = 1, res_hist%n_resonances
         call res_hist%resonances(i)%evaluate_distance (p, dist(i))
      end do
    end subroutine resonance_history_evaluate_distances
```

Use the distance to determine a Gaussian turnoff factor for a resonance. The factor is given by a Gaussian function e^{-d^2/σ^2}, where σ is the `gw` parameter multiplied by the resonance width, and d is the distance (see above). So, for $d = \sigma$, the factor is 0.37, and for $d = 2\sigma$ we get 0.018.

If the `gw` factor is less or equal to zero, return 1.

⟨*Resonances: resonance info: TBP*⟩+≡
```
    procedure :: evaluate_gaussian => resonance_info_evaluate_gaussian
```

⟨*Resonances: procedures*⟩+≡
```
    function resonance_info_evaluate_gaussian (res_info, p, gw) result (factor)
      class(resonance_info_t), intent(in) :: res_info
      type(vector4_t), dimension(:), intent(in) :: p
      real(default), intent(in) :: gw
      real(default) :: factor
      real(default) :: dist, w
      if (gw > 0) then
```

```
      w = res_info%flavor%get_width ()
      call res_info%evaluate_distance (p, dist)
      factor = exp (- (dist / (gw * w)) **2)
   else
      factor = 1
   end if
end function resonance_info_evaluate_gaussian
```

The Gaussian factor of the history is the product of all factors.

⟨*Resonances: resonance history: TBP*⟩+≡
```
   procedure :: evaluate_gaussian => resonance_history_evaluate_gaussian
```

⟨*Resonances: procedures*⟩+≡
```
   function resonance_history_evaluate_gaussian (res_hist, p, gw) result (factor)
     class(resonance_history_t), intent(in) :: res_hist
     type(vector4_t), dimension(:), intent(in) :: p
     real(default), intent(in) :: gw
     real(default), dimension(:), allocatable :: dist
     real(default) :: factor
     integer :: i
     factor = 1
     do i = 1, res_hist%n_resonances
        factor = factor * res_hist%resonances(i)%evaluate_gaussian (p, gw)
     end do
   end function resonance_history_evaluate_gaussian
```

Use the distances to determine whether the resonance history can qualify as on-shell. The criterion is whether the distance is greater than the number of width values as given by on_shell_limit.

⟨*Resonances: resonance info: TBP*⟩+≡
```
   procedure :: is_on_shell => resonance_info_is_on_shell
```

⟨*Resonances: procedures*⟩+≡
```
   function resonance_info_is_on_shell (res_info, p, on_shell_limit) &
        result (flag)
     class(resonance_info_t), intent(in) :: res_info
     type(vector4_t), dimension(:), intent(in) :: p
     real(default), intent(in) :: on_shell_limit
     logical :: flag
     real(default) :: dist
     call res_info%evaluate_distance (p, dist)
     flag = dist < on_shell_limit
   end function resonance_info_is_on_shell
```

⟨*Resonances: resonance history: TBP*⟩+≡
```
   procedure :: is_on_shell => resonance_history_is_on_shell
```

⟨*Resonances: procedures*⟩+≡
```
   function resonance_history_is_on_shell (res_hist, p, on_shell_limit) &
        result (flag)
     class(resonance_history_t), intent(in) :: res_hist
     type(vector4_t), dimension(:), intent(in) :: p
     real(default), intent(in) :: on_shell_limit
```

```
    logical :: flag
    integer :: i
    flag = .true.
    do i = 1, res_hist%n_resonances
       flag = flag .and. res_hist%resonances(i)%is_on_shell (p, on_shell_limit)
    end do
  end function resonance_history_is_on_shell
```

19.5.5 OMega restriction strings

One application of the resonance module is creating restriction strings that can
be fed into process definitions with the OMega generator. Since OMega counts
the incoming particles first, we have to supply **n_in** as an offset.

⟨*Resonances: resonance info: TBP*⟩+≡
```
    procedure :: as_omega_string => resonance_info_as_omega_string
```

⟨*Resonances: resonance history: TBP*⟩+≡
```
    procedure :: as_omega_string => resonance_history_as_omega_string
```

⟨*Resonances: procedures*⟩+≡
```
  function resonance_info_as_omega_string (res_info, n_in) result (string)
    class(resonance_info_t), intent(in) :: res_info
    integer, intent(in) :: n_in
    type(string_t) :: string
    integer :: i
    string = ""
    if (allocated (res_info%contributors%c)) then
       do i = 1, size (res_info%contributors%c)
          if (i > 1)  string = string // "+"
          string = string // str (res_info%contributors%c(i) + n_in)
       end do
       string = string // "~" // res_info%flavor%get_name ()
    end if
  end function resonance_info_as_omega_string

  function resonance_history_as_omega_string (res_hist, n_in) result (string)
    class(resonance_history_t), intent(in) :: res_hist
    integer, intent(in) :: n_in
    type(string_t) :: string
    integer :: i
    string = ""
    do i = 1, res_hist%n_resonances
       if (i > 1)  string = string // " && "
       string = string // res_hist%resonances(i)%as_omega_string (n_in)
    end do
  end function resonance_history_as_omega_string
```

19.5.6 Resonance history as tree

If we want to organize the resonances and their decay products, it can be useful
to have them explicitly as a tree structure. We implement this in the tradi-

tional event-record form with the resonances sorted by decreasing number of contributors, and their decay products added as an extra array.

⟨*Resonances: public*⟩+≡
```
    public :: resonance_tree_t
```

⟨*Resonances: types*⟩+≡
```
    type :: resonance_branch_t
       integer :: i = 0
       type(flavor_t) :: flv

Return the shifted indices of the resonance children for branch `i`. For a child which is itself a resonance, add `offset_r` to the index value. For the others, add `offset_o`. Combine both in a single array.

```

Transform a resonance history into a resonance tree. Algorithm:

1. Determine a mapping of the resonance array, such that in the new array the resonances are ordered by decreasing number of contributors.

2. Copy the flavor entries to the mapped array.

3. Scan all resonances and, for each one, find a resonance that is its parent. Since the resonances are ordered, later matches overwrite earlier ones. The last match is the correct one. Then scan again and, for each resonance, collect the resonances that have it as parent. This is the set of child resonances.

4. Analogously, scan all outgoing particles that appear in any of the contributors list. Determine their immediate parent as above, and set the child outgoing parents for the resonances, as above.

19.5.7 Resonance history set

This is an array of resonance histories. The elements are supposed to be unique. That is, entering a new element is successful only if the element does not already exist.

The current implementation uses a straightforward linear search for comparison. If this should become an issue, we may change the implementation to a hash table. To keep this freedom, the set should be an opaque object. In fact, we expect to use it as a transient data structure. Once the set is complete, we transform it into a contiguous array.

⟨*Resonances: public*⟩+≡
```
    public :: resonance_history_set_t

            call res_set%history(i)%to_tree (res_set%tree(i))
        end do
        res_set%complete = .true.
    end subroutine resonance_history_set_freeze
```

Determine the histories (in form of their indices in the array) that can be considered on-shell, given a set of momenta and a maximum distance. The distance from the resonance is measured in multiples of the resonance width.

Note that the momentum array must only contain the outgoing particles.

If a particular history is on-shell, but there is another history which contains this and also is on-shell, only the latter is retained.

⟨*Resonances: resonance history set: TBP*⟩+≡
```
    procedure :: determine_on_shell_histories &

19.6 Mappings

Mappings are objects that encode the transformation of the interval $(0, 1)$ to a physical variable m^2 or $\cos\theta$ (and back), as it is used in the phase space parameterization. The mapping objects contain fixed parameters, the associated methods implement the mapping and inverse mapping operations, including the computation of the Jacobian (phase space factor).

```

19.6.2 The Mapping type

Each mapping has a type (e.g., s-channel, infrared), a binary code (redundant, but useful for debugging), and a reference particle. The flavor code of this particle is stored for bookkeeping reasons, what matters are the mass and width of this particle. Furthermore, depending on the type, various mapping parameters can be set and used.

The parameters `a1` to `a3` (for m^2 mappings) and `b1` to `b3` (for $\cos\theta$ mappings) are values that are stored once to speed up the calculation, if `variable_limits` is false. The exact meaning of these parameters depends on the mapping type. The limits are fixed if there is a fixed c.m. energy.

⟨*Mappings: public*⟩+≡
```
    public :: mapping_t
```

⟨*Mappings: types*⟩+≡
```
    type :: mapping_t
      private
      integer :: type = NO_MAPPING
      integer(TC) :: bincode
      type(flavor_t) :: flv
      real(default) :: mass = 0
      real(default) :: width = 0
      logical :: a_unknown = .true.
      real(default) :: a1 = 0
      real(default) :: a2 = 0
      real(default) :: a3 = 0
      logical :: b_unknown = .true.
      real(default) :: b1 = 0
      real(default) :: b2 = 0
      real(default) :: b3 = 0
      logical :: variable_limits = .true.
    contains
    ⟨Mappings: mapping: TBP⟩
    end type mapping_t
```

The valid mapping types. The extra type **STEP_MAPPING** is used only internally.

⟨*Mappings: parameters*⟩≡

               end select
               select case (map%type)
               case (S_CHANNEL, T_CHANNEL, U_CHANNEL, &
                     STEP_MAPPING_E, STEP_MAPPING_H, &
                     COLLINEAR, INFRARED, RADIATION)
                  write (u, "(1x,A,3(" // FMT_19 // "))")  &
                        " a1/2/3 = ", map%a1, map%a2, map%a3
               end select
               select case (map%type)
               case (T_CHANNEL, U_CHANNEL, COLLINEAR)
                  write (u, "(1x,A,3(" // FMT_19 // "))")  &
                        " b1/2/3 = ", map%b1, map%b2, map%b3
               end select
            end if
         end if
      end if
    end subroutine mapping_write
```

19.6.4 Define a mapping

The initialization routine sets the mapping type and the particle (binary code and flavor code) for which the mapping applies (e.g., a Z resonance in branch #3).

⟨*Mappings: public*⟩+≡
```fortran
    public :: mapping_init
```

⟨*Mappings: procedures*⟩+≡

```
subroutine mapping_init (mapping, bincode, type, f, model)
  type(mapping_t), intent(inout) :: mapping
  integer(TC), intent(in) :: bincode
  type(string_t), intent(in) :: type
  integer, intent(in), optional :: f
  class(model_data_t), intent(in), optional, target :: model
  mapping%bincode = bincode
  select case (char (type))
  case ("s_channel");  mapping%type = S_CHANNEL
  case ("collinear");  mapping%type = COLLINEAR
  case ("infrared");   mapping%type = INFRARED
  case ("radiation");  mapping%type = RADIATION
  case ("t_channel");  mapping%type = T_CHANNEL
  case ("u_channel");  mapping%type = U_CHANNEL
  case ("step_exp");   mapping%type = STEP_MAPPING_E
  case ("step_hyp");   mapping%type = STEP_MAPPING_H
  case ("on_shell");   mapping%type = ON_SHELL
  case default
     call msg_bug ("Mappings: encountered undefined mapping key '" &
           // char (type) // "'")
  end select
  if (present (f) .and. present (model))  call mapping%flv%init (f, model)
end subroutine mapping_init
```

This sets the actual mass and width, using a parameter set. Since the auxiliary parameters will only be determined when the mapping is first called, they are marked as unknown.

⟨*Mappings: public*⟩+≡

```
public :: mapping_set_parameters
```

⟨*Mappings: procedures*⟩+≡

```
subroutine mapping_set_parameters (map, mapping_defaults, variable_limits)
  type(mapping_t), intent(inout) :: map
  type(mapping_defaults_t), intent(in) :: mapping_defaults
  logical, intent(in) :: variable_limits
  if (map%type /= NO_MAPPING) then
     map%mass  = map%flv%get_mass ()
     map%width = map%flv%get_width ()
     map%variable_limits = variable_limits
     map%a_unknown = .true.
     map%b_unknown = .true.
     select case (map%type)
     case (S_CHANNEL)
        if (map%mass <= 0) then
           call mapping_write (map)
           call msg_fatal &
                & (" S-channel resonance must have positive mass")
        else if (map%width <= 0) then
           call mapping_write (map)
           call msg_fatal &
                & (" S-channel resonance must have positive width")
        end if
     case (RADIATION)
```

```
            map%width = max (map%width, mapping_defaults%energy_scale)
         case (INFRARED, COLLINEAR)
            map%mass = max (map%mass, mapping_defaults%invariant_mass_scale)
         case (T_CHANNEL, U_CHANNEL)
            map%mass = max (map%mass, mapping_defaults%momentum_transfer_scale)
         end select
      end if
    end subroutine mapping_set_parameters
```

For a step mapping the mass and width are set directly, instead of being determined from the flavor parameter (which is meaningless here). They correspond to the effective upper bound of phase space due to a resonance, as opposed to the absolute upper bound.

⟨*Mappings: public*⟩+≡
```
    public :: mapping_set_step_mapping_parameters
```

⟨*Mappings: procedures*⟩+≡
```
    subroutine mapping_set_step_mapping_parameters (map, &
         mass, width, variable_limits)
      type(mapping_t), intent(inout) :: map
      real(default), intent(in) :: mass, width
      logical, intent(in) :: variable_limits
      select case (map%type)
      case (STEP_MAPPING_E, STEP_MAPPING_H)
         map%variable_limits = variable_limits
         map%a_unknown = .true.
         map%b_unknown = .true.
         map%mass = mass
         map%width = width
      end select
    end subroutine mapping_set_step_mapping_parameters
```

```

19.6.7 Mappings of the invariant mass

Inserting an x value between 0 and 1, we want to compute the corresponding invariant mass $m^2(x)$ and the jacobian, aka phase space factor $f(x)$. We also need the reverse operation.

In general, the phase space factor f is defined by

$$\frac{1}{s} \int_{m_{\min}^2}^{m_{\max}^2} dm^2 \, g(m^2) = \int_0^1 dx \, \frac{1}{s} \frac{dm^2}{dx} \, g(m^2(x)) = \int_0^1 dx \, f(x) \, g(x), \quad (19.8)$$

where thus

$$f(x) = \frac{1}{s} \frac{dm^2}{dx}. \quad (19.9)$$

With this mapping, a function of the form

$$g(m^2) = c \frac{dx(m^2)}{dm^2} \quad (19.10)$$

is mapped to a constant:

$$\frac{1}{s} \int_{m_{\min}^2}^{m_{\max}^2} dm^2 \, g(m^2) = \int_0^1 dx \, f(x) \, g(m^2(x)) = \int_0^1 dx \, \frac{c}{s}. \quad (19.11)$$

Here is the mapping routine. Input are the available energy squared `s`, the limits for m^2, and the x value. Output are the m^2 value and the phase space factor f.

    end select
  end subroutine mapping_compute_x_from_msq
```

Trivial mapping

We simply map the boundaries of the interval $(m_{\min}, m_{\max})$ to $(0, 1)$:

$$m^2 = (1 - x)m_{\min}^2 + xm_{\max}^2; \tag{19.12}$$

the inverse is

$$x = \frac{m^2 - m_{\min}^2}{m_{\max}^2 - m_{\min}^2}. \tag{19.13}$$

Hence

$$f(x) = \frac{m_{\max}^2 - m_{\min}^2}{s}, \tag{19.14}$$

and we have, as required,

$$f(x)\frac{dx}{dm^2} = \frac{1}{s}. \tag{19.15}$$

We store the constant parameters the first time the mapping is called – or, if limits vary, recompute them each time.

⟨Constants for trivial msq mapping⟩≡
```
    if (map%variable_limits .or. map%a_unknown) then
       map%a1 = 0
       map%a2 = msq_max - msq_min
       map%a3 = map%a2 / s
       map%a_unknown = .false.
    end if
```

⟨*Apply trivial msq mapping*⟩≡
```
    msq = (1-x) * msq_min + x * msq_max
    f = map%a3
```
⟨*Apply inverse trivial msq mapping*⟩≡
```
    if (map%a2 /= 0) then
       x = (msq - msq_min) / map%a2
    else
       x = 0
    end if
    f = map%a3
```

Resonance or step mapping does not make much sense if the resonance mass is outside the kinematical bounds. If this is the case, revert to NO_MAPPING. This is possible even if the kinematical bounds vary from event to event.

⟨*Modify mapping type if necessary*⟩≡
```
    select case (type)
    case (S_CHANNEL, STEP_MAPPING_E, STEP_MAPPING_H)
       msq0 = map%mass**2
       if (msq0 < msq_min .or. msq0 > msq_max)  type = NO_MAPPING
    end select
```

Breit-Wigner mapping

A Breit-Wigner resonance with mass M and width Γ is flattened by the following mapping:

This mapping does not make much sense if the resonance mass is too low. If this is the case, revert to NO_MAPPING. There is a tricky point with this if the mass is too high: msq_max is not a constant if structure functions are around. However, switching the type depending on the overall energy does not change the integral, it is just another branching point.

$$m^2 = M(M + t\Gamma), \tag{19.16}$$

where

$$t = \tan\left[(1-x)\arctan\frac{m_{\min}^2 - M^2}{M\Gamma} + x\arctan\frac{m_{\max}^2 - M^2}{M\Gamma}\right]. \tag{19.17}$$

The inverse:

$$x = \frac{\arctan\frac{m^2 - M^2}{M\Gamma} - \arctan\frac{m_{\min}^2 - M^2}{M\Gamma}}{\arctan\frac{m_{\max}^2 - M^2}{M\Gamma} - \arctan\frac{m_{\min}^2 - M^2}{M\Gamma}} \tag{19.18}$$

The phase-space factor of this transformation is

$$f(x) = \frac{M\Gamma}{s}\left(\arctan\frac{m_{\max}^2 - M^2}{M\Gamma} - \arctan\frac{m_{\min}^2 - M^2}{M\Gamma}\right)(1 + t^2). \tag{19.19}$$

This maps any function proportional to

$$g(m^2) = \frac{M\Gamma}{(m^2 - M^2)^2 + M^2\Gamma^2} \tag{19.20}$$

to a constant times $1/s$.

⟨*Constants for s-channel resonance mapping*⟩≡

    x = (atan (tmp) - map%a1) / (map%a2 - map%a1)
    f = map%a3 * (1 + tmp**2)
```

Mapping for massless splittings

This mapping accounts for approximately scale-invariant behavior where $\ln M^2$ is evenly distributed.

$$m^2 = m_{\min}^2 + M^2 \left(\exp(xL) - 1\right) \tag{19.21}$$

where

$$L = \ln\left(\frac{m_{\max}^2 - m_{\min}^2}{M^2} + 1\right). \tag{19.22}$$

The inverse:

$$x = \frac{1}{L} \ln\left(\frac{m^2 - m_{\min}^2}{M^2} + 1\right) \tag{19.23}$$

The constant M is a characteristic scale. Above this scale $(m^2 - m_{\min}^2 \gg M^2)$, this mapping behaves like $x \propto \ln m^2$, while below the scale it reverts to a linear mapping.

The phase-space factor is

$$f(x) = \frac{M^2}{s} \exp(xL) \, L. \tag{19.24}$$

A function proportional to

$$g(m^2) = \frac{1}{(m^2 - m_{\min}^2) + M^2} \tag{19.25}$$

is mapped to a constant, i.e., a simple pole near $m_{\min}$ with a regulator mass M.

This type of mapping is useful for massless collinear and infrared singularities, where the scale is stored as the mass parameter. In the radiation case

2282

(IR radiation off massive particle), the heavy particle width is the characteristic scale.

⟨*Constants for s-channel pole mapping*⟩≡
```
if (map%variable_limits .or. map%a_unknown) then
   if (type == RADIATION) then
      msq0 = map%width**2
   else
      msq0 = map%mass**2
   end if
   map%a1 = msq0
   map%a2 = log ((msq_max - msq_min) / msq0 + 1)
   map%a3 = map%a2 / s
   map%a_unknown = .false.
end if
```

⟨*Apply s-channel pole mapping*⟩≡
```
msq1 = map%a1 * exp (x * map%a2)
msq = msq1 - map%a1 + msq_min
f = map%a3 * msq1
```

⟨*Apply inverse s-channel pole mapping*⟩≡
```
msq1 = msq - msq_min + map%a1
x = log (msq1 / map%a1) / map%a2
f = map%a3 * msq1
```

Mapping for t-channel poles

This is also approximately scale-invariant, and we use the same type of mapping as before. However, we map $1/x$ singularities at both ends of the interval; again, the mapping becomes linear when the distance is less than M^2:

$$m^2 = \begin{cases} m_{\min}^2 + M^2 \left(\exp(xL) - 1 \right) & \text{for } 0 < x < \frac{1}{2} \\ m_{\max}^2 - M^2 \left(\exp((1-x)L) - 1 \right) & \text{for } \frac{1}{2} \leq x < 1 \end{cases} \tag{19.26}$$

where

$$L = 2 \ln \left(\frac{m_{\max}^2 - m_{\min}^2}{2M^2} + 1 \right). \tag{19.27}$$

The inverse:

$$x = \begin{cases} \frac{1}{L} \ln \left(\frac{m^2 - m_{\min}^2}{M^2} + 1 \right) & \text{for } m^2 < (m_{\max}^2 - m_{\min}^2)/2 \\ 1 - \frac{1}{L} \ln \left(\frac{m_{\max} - m^2}{M^2} + 1 \right) & \text{for } m^2 \geq (m_{\max}^2 - m_{\min}^2)/2 \end{cases} \tag{19.28}$$

The phase-space factor is

$$f(x) = \begin{cases} \frac{M^2}{s} \exp(xL) L. & \text{for } 0 < x < \frac{1}{2} \\ \frac{M^2}{s} \exp((1-x)L) L. & \text{for } \frac{1}{2} \leq x < 1 \end{cases} \tag{19.29}$$

A (continuous) function proportional to

$$g(m^2) = \begin{cases} 1/(m^2 - m_{\min}^2) + M^2) & \text{for } m^2 < (m_{\max}^2 - m_{\min}^2)/2 \\ 1/((m_{\max}^2 - m^2) + M^2) & \text{for } m^2 \leq (m_{\max}^2 - m_{\min}^2)/2 \end{cases} \tag{19.30}$$

is mapped to a constant by this mapping, i.e., poles near both ends of the interval.

⟨*Constants for t-channel pole mapping*⟩≡
```
    if (map%variable_limits .or. map%a_unknown) then
       msq0 = map%mass**2
       map%a1 = msq0

    end if
    f = map%a3 * msq1
```

19.6.8 Step mapping

Step mapping is useful when the allowed range for a squared-mass variable is large, but only a fraction at the lower end is populated because the particle in question is an (off-shell) decay product of a narrow resonance. I.e., if the resonance was forced to be on-shell, the upper end of the range would be the resonance mass, minus the effective (real or resonance) mass of the particle(s) in the sibling branch of the decay.

The edge of this phase space section has a width which is determined by the width of the parent, plus the width of the sibling branch. (The widths might be added in quadrature, but this precision is probably not important.)

Fermi function

A possible mapping is derived from the Fermi function which has precisely this behavior. The Fermi function is given by

$$f(x) = \frac{1}{1 + \exp \frac{x - \mu}{\gamma}} \tag{19.31}$$

where x is taken as the invariant mass squared, μ is the invariant mass squared of the edge, and γ is the effective width which is given by the widths of the

parent and the sibling branch. (Widths might be added in quadrature, but we do not require this level of precision.)

$$x = \frac{m^2 - m_{\min}^2}{\Delta m^2} \tag{19.32}$$

$$\mu = \frac{m_{\max,\text{eff}}^2 - m_{\min}^2}{\Delta m^2} \tag{19.33}$$

$$\gamma = \frac{2m_{\max,\text{eff}}\Gamma}{\Delta m^2} \tag{19.34}$$

with

$$\Delta m^2 = m_{\max}^2 - m_{\min}^2 \tag{19.35}$$

m^2 is thus given by

$$m^2(x) = x m_{\max}^2 + (1 - x) m_{\min}^2 \tag{19.36}$$

For the mapping, we compute the integral $g(x)$ of the Fermi function, normalized such that $g(0) = 0$ and $g(1) = 1$. We introduce the abbreviations

$$\alpha = 1 - \gamma \ln \frac{1 + \beta e^{1/\gamma}}{1 + \beta} \tag{19.37}$$

$$\beta = e^{-\mu/\gamma} \tag{19.38}$$

and obtain

$$g(x) = \frac{1}{\alpha} \left(x - \gamma \ln \frac{1 + \beta e^{x/\gamma}}{1 + \beta} \right) \tag{19.39}$$

The actual mapping is the inverse function $h(y) = g^{-1}(y)$,

$$h(y) = -\gamma \ln \left(e^{-\alpha y/\gamma} (1 + \beta) - \beta \right) \tag{19.40}$$

The Jacobian is

$$\frac{dh}{dy} = \alpha \left(1 - e^{\alpha y/\gamma} \frac{\beta}{1 + \beta} \right)^{-1} \tag{19.41}$$

which is equal to $1/(dg/dx)$, namely

$$\frac{dg}{dx} = \frac{1}{\alpha} \frac{1}{1 + \beta e^{x/\gamma}} \tag{19.42}$$

The final result is

$$\int_{m_{\min}^2}^{m_{\max}^2} dm^2 \, F(m^2) = \Delta m^2 \int_0^1 dx \, F(m^2(x)) \tag{19.43}$$

$$= \Delta m^2 \int_0^1 dy \, F(m^2(h(y))) \frac{dh}{dy} \tag{19.44}$$

Here is the implementation. We fill a1, a2, a3 with α, β, γ, respectively.

⟨*Constants for exponential step mapping*⟩≡
```
if (map%variable_limits .or. map%a_unknown) then
   map%a3 = max (2 * map%mass * map%width / (msq_max - msq_min), 0.01_default)

```
tmp = exp (- x * map%a1 / map%a3) * (1 + map%a2)
z = - map%a3 * log (tmp - map%a2)
msq  = z * msq_max + (1 - z) * msq_min
f = map%a1 / (1 - map%a2 / tmp) * (msq_max - msq_min) / s
```

⟨*Apply inverse exponential step mapping*⟩≡
```
z = (msq - msq_min) / (msq_max - msq_min)
tmp = 1 + map%a2 * exp (z / map%a3)
x = (z - map%a3 * log (tmp / (1 + map%a2))) &
    / map%a1
f = map%a1 * tmp * (msq_max - msq_min) / s
```

Hyperbolic mapping

The Fermi function has the drawback that it decreases exponentially. It might be preferable to take a function with a power-law decrease, such that the high-mass region is not completely depopulated.

Here, we start with the actual mapping which we take as

$$h(y) = \frac{b}{a - y} - \frac{b}{a} + \mu y \tag{19.45}$$

with the abbreviation

$$a = \frac{1}{2}\left(1 + \sqrt{1 + \frac{4b}{1 - \mu}}\right) \tag{19.46}$$

This is a hyperbola in the xy plane. The derivative is

$$\frac{dh}{dy} = \frac{b}{(a - y)^2} + \mu \tag{19.47}$$

The constants correspond to

$$\mu = \frac{m_{\mathrm{max,eff}}^2 - m_{\mathrm{min}}^2}{\Delta m^2} \tag{19.48}$$

$$b = \frac{1}{\mu}\left(\frac{2m_{\mathrm{max,eff}}\Gamma}{\Delta m^2}\right)^2 \tag{19.49}$$

The inverse function is the solution of a quadratic equation,

$$g(x) = \frac{1}{2}\left[\left(a + \frac{x}{\mu} + \frac{b}{a\mu}\right) - \sqrt{\left(a - \frac{x}{\mu}\right)^2 + 2\frac{b}{a\mu}\left(a + \frac{x}{\mu}\right) + \left(\frac{b}{a\mu}\right)^2}\right] \tag{19.50}$$

The constants $a_{1,2,3}$ are identified with a, b, μ.

⟨*Constants for hyperbolic step mapping*⟩≡

              + tmp**2)) / 2
    f = (map%a2 / (map%a1 - x)**2 + map%a3) * (msq_max - msq_min) / s
```

19.6.9 Mappings of the polar angle

The other type of singularity, a simple pole just outside the integration region, can occur in the integration over $\cos\theta$. This applies to exchange of massless (or light) particles.

Double poles (Coulomb scattering) are also possible, but only in certain cases. These are also handled by the single-pole mapping.

The mapping is analogous to the previous m^2 pole mapping, but with a different normalization and notation of variables:

$$\frac{1}{2} \int_{-1}^{1} d\cos\theta \, g(\theta) = \int_{0}^{1} dx \, \frac{d\cos\theta}{dx} \, g(\theta(x)) = \int_{0}^{1} dx \, f(x) \, g(x), \qquad (19.51)$$

where thus

$$f(x) = \frac{1}{2} \frac{d\cos\theta}{dx}. \qquad (19.52)$$

With this mapping, a function of the form

$$g(\theta) = c \frac{dx(\cos\theta)}{d\cos\theta} \qquad (19.53)$$

is mapped to a constant:

$$\int_{-1}^{1} d\cos\theta \, g(\theta) = \int_{0}^{1} dx \, f(x) \, g(\theta(x)) = \int_{0}^{1} dx \, c. \qquad (19.54)$$

```

Trivial mapping

This is just the mapping of the interval $(-1, 1)$ to $(0, 1)$:

$$\cos\theta = -1 + 2x \tag{19.55}$$

and

$$f(x) = 1 \tag{19.56}$$

with the inverse

$$x = \frac{1 + \cos\theta}{2} \tag{19.57}$$

⟨*Apply trivial ct mapping*⟩≡
```
    tmp = 2 * (1-x)
    ct = 1 - tmp
    st = sqrt (tmp * (2-tmp))
    f = 1
```

⟨*Apply inverse trivial ct mapping*⟩≡
```
    x = (ct + 1) / 2
    f = 1
```

Pole mapping

As above for m^2, we simultaneously map poles at both ends of the $\cos\theta$ interval. The formulae are completely analogous:

$$\cos\theta = \begin{cases} \frac{M^2}{s}\left[\exp(xL) - 1\right] - 1 & \text{for } x < \frac{1}{2} \\ -\frac{M^2}{s}\left[\exp((1-x)L) - 1\right] + 1 & \text{for } x \geq \frac{1}{2} \end{cases} \tag{19.58}$$

where

$$L = 2\ln\frac{M^2 + s}{M^2}. \tag{19.59}$$

Inverse:

$$x = \begin{cases} \frac{1}{2L}\ln\frac{1+\cos\theta+M^2/s}{M^2/s} & \text{for } \cos\theta < 0 \\ 1 - \frac{1}{2L}\ln\frac{1-\cos\theta+M^2/s}{M^2/s} & \text{for } \cos\theta \geq 0 \end{cases} \tag{19.60}$$

The phase-space factor:

$$f(x) = \begin{cases} \frac{M^2}{s}\exp(xL)\,L & \text{for } x < \frac{1}{2} \\ \frac{M^2}{s}\exp((1-x)L)\,L & \text{for } x \geq \frac{1}{2} \end{cases} \tag{19.61}$$

⟨*Constants for ct pole mapping*⟩≡
```
if (map%variable_limits .or. map%b_unknown) then
   map%b1 = map%mass**2 / s
   map%b2 = log ((map%b1 + 1) / map%b1)
   map%b3 = 0
   map%b_unknown = .false.
end if
```

⟨*Apply ct pole mapping*⟩≡
```
if (x < .5_default) then
   ct1 = map%b1 * exp (2 * x * map%b2)
   ct = ct1 - map%b1 - 1
else
   ct1 = map%b1 * exp (2 * (1-x) * map%b2)
   ct = -(ct1 - map%b1) + 1
end if
if (ct >= -1 .and. ct <= 1) then
   st = sqrt (1 - ct**2)
   f = ct1 * map%b2
else
   ct = 1;  st = 0;  f = 0
end if
```

⟨*Apply inverse ct pole mapping*⟩≡
```
if (ct < 0) then
   ct1 = ct + map%b1 + 1
   x = log (ct1 / map%b1) / (2 * map%b2)
else
   ct1 = -ct + map%b1 + 1
   x = 1 - log (ct1 / map%b1) / (2 * map%b2)
end if
f = ct1 * map%b2
```

19.7 Phase-space trees

The phase space evaluation is organized in terms of trees, where each branch corresponds to three integrations: m^2, $\cos\theta$, and ϕ. The complete tree thus makes up a specific parameterization of the multidimensional phase-space integral. For the multi-channel integration, the phase-space tree is a single channel.

The trees imply mappings of formal Feynman tree graphs into arrays of integer numbers: Each branch, corresponding to a particular line in the graph, is assigned an integer code c (with kind value $\mathtt{TC}$ = tree code).

In this integer, each bit determines whether a particular external momentum flows through the line. The external branches therefore have codes $1, 2, 4, 8, \ldots$. An internal branch has those bits ORed corresponding to the momenta flowing through it. For example, a branch with momentum $p_1 + p_4$ has code $2^0 + 2^3 = 1 + 8 = 9$.

There is a two-fold ambiguity: Momentum conservation implies that the branch with code

$$c_0 = \sum_{i=1}^{n(\mathrm{ext})} 2^{i-1} \tag{19.62}$$

i.e. the branch with momentum $p_1 + p_2 + \ldots p_n$ has momentum zero, which is equivalent to tree code 0 by definition. Correspondingly,

$$c \quad \text{and} \quad c_0 - c = c \text{ XOR } c_0 \tag{19.63}$$

are equivalent. E.g., if there are five externals with codes $c = 1, 2, 4, 8, 16$, then $c = 9$ and $\bar{c} = 31 - 9 = 22$ are equivalent.

This ambiguity may be used to assign a direction to the line: If all momenta are understood as outgoing, $c = 9$ in the example above means $p_1 + p_4$, but $c = 22$ means $p_2 + p_3 + p_5 = -(p_1 + p_4)$.

Here we make use of the ambiguity in a slightly different way. First, the initial particles are singled out as those externals with the highest bits, the IN-bits. (Here: 8 and 16 for a $2 \to 3$ scattering process, 16 only for a $1 \to 4$ decay.) Then we invert those codes where all IN-bits are set. For a decay process this maps each tree of an equivalence class onto a unique representative (that one with the smallest integer codes). For a scattering process we proceed further:

The ambiguity remains in all branches where only one IN-bit is set, including the initial particles. If there are only externals with this property, we have an s-channel graph which we leave as it is. In all other cases, an internal with only one IN-bit is a t-channel line, which for phase space integration should be associated with one of the initial momenta as a reference axis. We take that one whose bit is set in the current tree code. (E.g., for branch $c = 9$ we use the initial particle $c = 8$ as reference axis, whereas for the same branch we would take $c = 16$ if it had been assigned $\bar{c} = 31 - 9 = 22$ as tree code.) Thus, different ways of coding the same t-channel graph imply different phase space parameterizations.

s-channel graphs have a unique parameterization. The same sets of parameterizations are used for t-channel graphs, except for the reference frames of their angular parts. We map each t-channel graph onto an s-channel graph as follows:

Working in ascending order, for each t-channel line (whose code has exactly one IN-bit set) the attached initial line is flipped upstream, while the outgoing

line is flipped downstream. (This works only if *t*-channel graphs are always parameterized beginning at their outer vertices, which we require as a restriction.) After all possible flips have been applied, we have an *s*-channel graph. We only have to remember the initial particle a vertex was originally attached to.

19.7.2   The phase-space tree type

Definition

In the concrete implementation, each branch c may have two *daughters* c_1 and c_2 such that $c_1 + c_2 = c$, a *sibling* c_s and a *mother* c_m such that $c + c_s = c_m$, and a *friend* which is kept during flips, such that it can indicate a fixed reference frame. Absent entries are set $c = 0$.

First, declare the branch type. There is some need to have this public. Give initializations for all components, so no `init` routine is necessary. The branch has some information about the associated coordinates and about connections.

⟨*PHS trees: types*⟩+≡

```
type :: phs_branch_t
   private
   logical :: set = .false.
   logical :: inverted_decay = .false.
   logical :: inverted_axis = .false.
   integer(TC) :: mother = 0
   integer(TC) :: sibling = 0
   integer(TC) :: friend = 0
   integer(TC) :: origin = 0
   integer(TC), dimension(2) :: daughter = 0
   integer :: firstborn = 0
   logical :: has_children = .false.
   logical :: has_friend = .false.
   logical :: is_real = .false.
end type phs_branch_t
```

The tree type: No initialization, this is done by **phs_tree_init**. In addition to the branch array which

The branches are collected in an array which holds all possible branches, of which only a few are set. After flips have been applied, the branch $c_M = \sum_{i=1}^{n(\text{fin})} 2^{i-1}$ must be there, indicating the mother of all decay products. In addition, we should check for consistency at the beginning.

n_branches is the number of those actually set. **n_externals** defines the number of significant bit, and **mask** is a code where all bits are set. Analogous: **n_in** and **mask_in** for the incoming particles.

The **mapping** array contains the mappings associated to the branches (corresponding indices). The array **mass_sum** contains the sum of the real masses of the external final-state particles associated to the branch. During phase-space evaluation, this determines the boundaries.

⟨*PHS trees: public*⟩+≡

```
public :: phs_tree_t
```

⟨*PHS trees: types*⟩+≡

```
type :: phs_tree_t
   private
   integer :: n_branches, n_externals, n_in, n_msq, n_angles
   integer(TC) :: n_branches_tot, n_branches_out
   integer(TC) :: mask, mask_in, mask_out
   type(phs_branch_t), dimension(:), allocatable :: branch
   type(mapping_t), dimension(:), allocatable :: mapping
   real(default), dimension(:), allocatable :: mass_sum
   real(default), dimension(:), allocatable :: effective_mass
   real(default), dimension(:), allocatable :: effective_width
   logical :: real_phsp = .false.
   integer, dimension(:), allocatable :: momentum_link
 contains
 ⟨PHS trees: phs tree: TBP⟩
end type phs_tree_t
```

The maximum number of external particles that can be represented is related to the bit size of the integer that stores binary codes. With the default integer of 32 bit on common machines, this is more than enough space. If TC is actually the default integer kind, there is no need to keep it separate, but doing so marks this as a special type of integer. So, just state that the maximum number is 32:

⟨*Limits: public parameters*⟩≡
```
    integer, parameter, public :: MAX_EXTERNAL = 32
```

Constructor and destructor

Allocate memory for a phase-space tree with given number of externals and incoming. The number of allocated branches can easily become large, but appears manageable for realistic cases, e.g., for n_in=2 and n_out=8 we get $2^{10}-1 = 1023$.

⟨*PHS trees: public*⟩+≡
```
    public :: phs_tree_init
    public :: phs_tree_final
```

Here we set the masks for incoming and for all externals.

⟨*PHS trees: phs tree: TBP*⟩≡
```
    procedure :: init => phs_tree_init
    procedure :: final => phs_tree_final
```

⟨*PHS trees: procedures*⟩+≡
```
    elemental subroutine phs_tree_init (tree, n_in, n_out, n_masses, n_angles)
      class(phs_tree_t), intent(inout) :: tree
      integer, intent(in) :: n_in, n_out, n_masses, n_angles
      integer(TC) :: i
      tree%n_externals = n_in + n_out
      tree%n_branches_tot = 2**(n_in+n_out) - 1
      tree%n_branches_out = 2**n_out - 1
      tree%mask = 0
      do i = 0, n_in + n_out - 1
         tree%mask = ibset (tree%mask, i)
      end do
      tree%n_in = n_in
      tree%mask_in = 0

                 &    '(axis '//sign_axis//')'
         end if
      else
         write(u,'(5X,I0)') k
      end if
    end subroutine phs_branch_write
```

19.7.3 PHS tree setup

Transformation into an array of branch codes and back

Assume that the tree/array has been created before with the appropriate length
and is empty.

⟨*PHS trees: public*⟩+≡
```fortran
    public :: phs_tree_from_array
```

⟨*PHS trees: phs tree: TBP*⟩+≡
```
    procedure :: from_array => phs_tree_from_array
```

⟨*PHS trees: procedures*⟩+≡
```
    subroutine phs_tree_from_array (tree, a)
      class(phs_tree_t), intent(inout) :: tree
      integer(TC), dimension(:), intent(in) :: a
      integer :: i
      integer(TC) :: k
```
⟨*Set branches from array* a⟩
⟨*Set external branches if necessary*⟩
⟨*Check number of branches*⟩
⟨*Determine the connections*⟩
```
    contains
```
⟨*Subroutine: set relatives*⟩
```
    end subroutine phs_tree_from_array
```

First, set all branches specified by the user. If all IN-bits are set, we invert the branch code.

⟨*Set branches from array* a⟩≡
```
    do i=1, size(a)
      k = a(i)
      if (iand(k, tree%mask_in) == tree%mask_in)  k = ieor(tree%mask, k)
      tree%branch(k)%set = .true.
      tree%n_branches = tree%n_branches+1
    end do
```

The external branches are understood, so set them now if not yet done. In all cases ensure that the representative with one bit set is used, except for decays where the in-particle is represented by all OUT-bits set instead.

⟨*Set external branches if necessary*⟩≡
```
    do i=0, tree%n_externals-1
      k = ibset(0,i)
      if (iand(k, tree%mask_in) == tree%mask_in)  k = ieor(tree%mask, k)
      if (tree%branch(ieor(tree%mask, k))%set) then
         tree%branch(ieor(tree%mask, k))%set = .false.
         tree%branch(k)%set = .true.
      else if (.not.tree%branch(k)%set) then
         tree%branch(k)%set = .true.
         tree%n_branches = tree%n_branches+1
      end if
    end do
```

Now the number of branches set can be checked. Here we assume that the tree is binary. For three externals there are three branches in total, and for each additional external branch we get another internal one.

⟨*Check number of branches*⟩≡
```
    if (tree%n_branches /= tree%n_externals*2-3) then
       call phs_tree_write (tree)
       call msg_bug &
            & (" Wrong number of branches set in phase space tree")
    end if
```

For all branches that are set, except for the externals, we try to find the daughter branches:

⟨*Determine the connections*⟩≡

```
do k=1, size (tree%branch)
   if (tree%branch(k)%set .and. tc_decay_level (k) /= 1) then
      call branch_set_relatives(k)
   end if
end do
```

To this end, we scan all codes less than the current code, whether we can find two branches which are set and which together give the current code. After that, the tree may still not be connected, but at least we know if a branch does not have daughters: This indicates some inconsistency.

The algorithm ensures that, at this stage, the first daughter has a smaller code value than the second one.

⟨*Subroutine: set relatives*⟩≡

```
subroutine branch_set_relatives (k)
  integer(TC), intent(in) :: k
  integer(TC) :: m,n
  do m=1, k-1
     if(iand(k,m)==m) then
        n = ieor(k,m)
        if ( tree%branch(m)%set .and. tree%branch(n)%set ) then
           tree%branch(k)%daughter(1) = m;  tree%branch(k)%daughter(2) = n
           tree%branch(m)%mother      = k;  tree%branch(n)%mother      = k
           tree%branch(m)%sibling     = n;  tree%branch(n)%sibling     = m
           tree%branch(k)%has_children = .true.
           return
        end if
     end if
  end do
  call phs_tree_write (tree)
  call msg_bug &
       & (" Missing daughter branch(es) in phase space tree")
end subroutine branch_set_relatives
```

The inverse: this is trivial, fortunately.

Flip *t*-channel into *s*-channel

Flipping the tree is done upwards, beginning from the decay products. First we select a *t*-channel branch `k`: one which is set, which does have an IN-bit, and which is not an external particle.

Next, we determine the adjacent in-particle (called the 'friend' `f` here, since it will provide the reference axis for the angular integration). In addition, we look for the 'mother' and 'sibling' of this particle. If the latter field is empty, we select the (unique) other out-particle which has no mother, calling the internal subroutine `find_orphan`.

The flip is done as follows: We assume that the first daughter `d` is an *s*-channel line, which is true if the daughters are sorted. This will stay the first daughter. The second one is a *t*-channel line; it is exchanged with the 'sibling'

s. The new line which replaces the branch `k` is just the sum of `s` and `d`. In addition, we have to rearrange the relatives of `s` and `d`, as well of `f`.

Finally, we flip 'sibling' and 'friend' and set the new *s*-channel branch `n` which replaces the *t*-channel branch `k`. After this is complete, we are ready to execute another flip.

[Although the friend is not needed for the final flip, since it would be an initial particle anyway, we need to know whether we have *t*- or *u*-channel.]

⟨*PHS trees: public*⟩+≡
```
    public :: phs_tree_flip_t_to_s_channel
```

⟨*PHS trees: procedures*⟩+≡
```
    subroutine phs_tree_flip_t_to_s_channel (tree)
      type(phs_tree_t), intent(inout) :: tree
      integer(TC) :: k, f, m, n, d, s
      if (tree%n_in == 2) then
         FLIP: do k=3, tree%mask-1
            if (.not. tree%branch(k)%set) cycle FLIP
            f = iand(k,tree%mask_in)
            if (f==0 .or. f==k) cycle FLIP
            m = tree%branch(k)%mother
            s = tree%branch(k)%sibling
            if (s==0) call find_orphan(s)
            d = tree%branch(k)%daughter(1)
            n = ior(d,s)
            tree%branch(k)%set = .false.
            tree%branch(n)%set = .true.
            tree%branch(n)%origin = k
            tree%branch(n)%daughter(1) = d; tree%branch(d)%mother  = n
            tree%branch(n)%daughter(2) = s; tree%branch(s)%mother  = n
            tree%branch(n)%has_children = .true.
            tree%branch(d)%sibling = s;  tree%branch(s)%sibling = d
            tree%branch(n)%sibling = f;  tree%branch(f)%sibling = n
            tree%branch(n)%mother      = m
            tree%branch(f)%mother      = m
            if (m/=0) then
               tree%branch(m)%daughter(1) = n
               tree%branch(m)%daughter(2) = f
            end if
            tree%branch(n)%friend = f
            tree%branch(n)%has_friend = .true.
            tree%branch(n)%firstborn = 2
         end do FLIP
      end if
    contains
      subroutine find_orphan(s)
        integer(TC) :: s
        do s=1, tree%mask_out
           if (tree%branch(s)%set .and. tree%branch(s)%mother==0) return
        end do
        call phs_tree_write (tree)
        call msg_bug (" Can't flip phase space tree to channel")
      end subroutine find_orphan
    end subroutine phs_tree_flip_t_to_s_channel
```

After the tree has been flipped, one may need to determine what has become of a particular *t*-channel branch. This function gives the bincode of the flipped tree. If the original bincode does not contain IN-bits, we leave it as it is.

⟨*PHS trees: procedures*⟩+≡

```
function tc_flipped (tree, kt) result (ks)
  type(phs_tree_t), intent(in) :: tree
  integer(TC), intent(in) :: kt
  integer(TC) :: ks
  if (iand (kt, tree%mask_in) == 0) then
     ks = kt
  else
     ks = tree%branch(iand (kt, tree%mask_out))%mother
  end if
end function tc_flipped
```

Scan a tree and make sure that the first daughter has always a smaller code than the second one. Furthermore, delete any `friend` entry in the root branch – this branching has the incoming particle direction as axis anyway. Keep track of reordering by updating `inverted_axis`, `inverted_decay` and `firstborn`.

⟨*PHS trees: public*⟩+≡

```
public :: phs_tree_canonicalize
```

⟨*PHS trees: procedures*⟩+≡

```
subroutine phs_tree_canonicalize (tree)
  type(phs_tree_t), intent(inout) :: tree
  integer :: n_out
  integer(TC) :: k_out
  call branch_canonicalize (tree%branch(tree%mask_out))
  n_out = tree%n_externals - tree%n_in
  k_out = tree%mask_out
  if (tree%branch(k_out)%has_friend &
       & .and. tree%branch(k_out)%friend == ibset (0, n_out)) then
     tree%branch(k_out)%inverted_axis = .not.tree%branch(k_out)%inverted_axis
  end if
  tree%branch(k_out)%has_friend = .false.
  tree%branch(k_out)%friend = 0
contains
  recursive subroutine branch_canonicalize (b)
    type(phs_branch_t), intent(inout) :: b
    integer(TC) :: d1, d2
    if (b%has_children) then
       d1 = b%daughter(1)
       d2 = b%daughter(2)
       if (d1 > d2) then
          b%daughter(1) = d2
          b%daughter(2) = d1
          b%inverted_decay = .not.b%inverted_decay
          if (b%firstborn /= 0)  b%firstborn = 3 - b%firstborn
       end if
       call branch_canonicalize (tree%branch(b%daughter(1)))
       call branch_canonicalize (tree%branch(b%daughter(2)))
    end if
  end subroutine branch_canonicalize
```

```
        end subroutine phs_tree_canonicalize
```

Mappings

Initialize a mapping for the current tree. This is done while reading from file, so the mapping parameters are read, but applied to the flipped tree. Thus, the size of the array of mappings is given by the number of outgoing particles only.

⟨*PHS trees: public*⟩+≡
```
    public :: phs_tree_init_mapping
```

⟨*PHS trees: phs tree: TBP*⟩+≡
```
    procedure :: init_mapping => phs_tree_init_mapping
```

⟨*PHS trees: procedures*⟩+≡
```
    subroutine phs_tree_init_mapping (tree, k, type, pdg, model)
      class(phs_tree_t), intent(inout) :: tree
      integer(TC), intent(in) :: k
      type(string_t), intent(in) :: type
      integer, intent(in) :: pdg
      class(model_data_t), intent(in), target :: model
      integer(TC) :: kk
      kk = tc_flipped (tree, k)
      call mapping_init (tree%mapping(kk), kk, type, pdg, model)
    end subroutine phs_tree_init_mapping
```

Set the physical parameters for the mapping, using a specific parameter set. Also set the mass sum array.

⟨*PHS trees: public*⟩+≡
```
    public :: phs_tree_set_mapping_parameters
```

⟨*PHS trees: phs tree: TBP*⟩+≡
```
    procedure :: set_mapping_parameters => phs_tree_set_mapping_parameters
```

⟨*PHS trees: procedures*⟩+≡
```
    subroutine phs_tree_set_mapping_parameters &
         (tree, mapping_defaults, variable_limits)
      class(phs_tree_t), intent(inout) :: tree
      type(mapping_defaults_t), intent(in) :: mapping_defaults
      logical, intent(in) :: variable_limits
      integer(TC) :: k
      do k = 1, tree%n_branches_out
         call mapping_set_parameters &
              (tree%mapping(k), mapping_defaults, variable_limits)
      end do
    end subroutine phs_tree_set_mapping_parameters
```

Return the mapping for the sum of all outgoing particles. This should either be no mapping or a global s-channel mapping.

⟨*PHS trees: public*⟩+≡
```
    public :: phs_tree_assign_s_mapping
```

⟨*PHS trees: procedures*⟩+≡
```
    subroutine phs_tree_assign_s_mapping (tree, mapping)
      type(phs_tree_t), intent(in) :: tree
      type(mapping_t), intent(out) :: mapping
      mapping = tree%mapping(tree%mask_out)
    end subroutine phs_tree_assign_s_mapping
```

Kinematics

Fill the mass sum array, starting from the external particles and working down to the tree root. For each bincode `k` we scan the bits in `k`; if only one is set, we take the physical mass of the corresponding external particle; if more then one is set, we sum up the two masses (which we know have already been set).

⟨*PHS trees: public*⟩+≡
```
    public :: phs_tree_set_mass_sum
```

⟨*PHS trees: phs tree: TBP*⟩+≡
```
    procedure :: set_mass_sum => phs_tree_set_mass_sum
```

⟨*PHS trees: procedures*⟩+≡
```
    subroutine phs_tree_set_mass_sum (tree, flv)
      class(phs_tree_t), intent(inout) :: tree
      type(flavor_t), dimension(:), intent(in) :: flv
      integer(TC) :: k
      integer :: i
      tree%mass_sum = 0
      do k = 1, tree%n_branches_out
        do i = 0, size (flv) - 1
          if (btest(k,i)) then
            if (ibclr(k,i) == 0) then
              tree%mass_sum(k) = flv(i+1)%get_mass ()
            else
              tree%mass_sum(k) = &
                    tree%mass_sum(ibclr(k,i)) + tree%mass_sum(ibset(0,i))
            end if
            exit
          end if
        end do
      end do
    end subroutine phs_tree_set_mass_sum
```

Set the effective masses and widths. For each non-resonant branch in a tree, the effective mass is equal to the sum of the effective masses of the children (and analogous for the width). External particles have their real mass and width zero. For resonant branches, we insert mass and width from the corresponding mapping.

This routine has `phs_tree_set_mass_sum` and `phs_tree_set_mapping_parameters` as prerequisites.

⟨*PHS trees: public*⟩+≡
```
    public :: phs_tree_set_effective_masses
```

⟨*PHS trees: phs tree: TBP*⟩+≡
```
    procedure :: set_effective_masses => phs_tree_set_effective_masses
```

⟨PHS trees: procedures⟩+≡

```
subroutine phs_tree_set_effective_masses (tree)
  class(phs_tree_t), intent(inout) :: tree
  tree%effective_mass = 0
  tree%effective_width = 0
  call set_masses_x (tree%mask_out)
contains
  recursive subroutine set_masses_x (k)
    integer(TC), intent(in) :: k
    integer(TC) :: k1, k2
    if (tree%branch(k)%has_children) then
       k1 = tree%branch(k)%daughter(1)
       k2 = tree%branch(k)%daughter(2)
       call set_masses_x (k1)
       call set_masses_x (k2)
       if (mapping_is_s_channel (tree%mapping(k))) then
          tree%effective_mass(k) = mapping_get_mass (tree%mapping(k))
          tree%effective_width(k) = mapping_get_width (tree%mapping(k))
       else
          tree%effective_mass(k) = &
               tree%effective_mass(k1) + tree%effective_mass(k2)
          tree%effective_width(k) = &
               tree%effective_width(k1) + tree%effective_width(k2)
       end if
    else
       tree%effective_mass(k) = tree%mass_sum(k)
    end if
  end subroutine set_masses_x
end subroutine phs_tree_set_effective_masses
```

Define step mappings, recursively, for the decay products of all intermediate resonances. Step mappings account for the fact that a branch may originate from a resonance, which almost replaces the upper limit on the possible invariant mass. The step mapping implements a smooth cutoff that interpolates between the resonance and the real kinematic limit. The mapping width determines the sharpness of the cutoff.

Step mappings are inserted only for branches that are not mapped otherwise.

At each branch, we record the mass that is effectively available for phase space, by taking the previous limit and subtracting the effective mass of the sibling branch. Widths are added, not subtracted.

If we encounter a resonance decay, we discard the previous limit and replace it by the mass and width of the resonance, also subtracting the sibling branch.

Initially, the limit is zero, so it becomes negative at any branch. Only if there is a resonance, the limit becomes positive. Whenever the limit is positive, and the current branch decays, we activate a step mapping for the current branch.

As a result, step mappings are implemented for all internal lines that originate from an intermediate resonance decay.

The flag `variable_limits` applies to the ultimate limit from the available energy, not to the intermediate resonances whose masses are always fixed.

This routine requires **phs_tree_set_effective_masses**

⟨PHS trees: public⟩+≡

```
public :: phs_tree_set_step_mappings
```

⟨PHS trees: procedures⟩+≡

```
subroutine phs_tree_set_step_mappings (tree, exp_type, variable_limits)
  type(phs_tree_t), intent(inout) :: tree

```

```
      end if
    end subroutine set_step_mappings_x
  end subroutine phs_tree_set_step_mappings
```

Resonance structure

We identify the resonances within a tree as the set of s-channel mappings. The
resonance_history_t type serves as the result container.

⟨*PHS trees: phs tree: TBP*⟩+≡

```
    procedure :: extract_resonance_history => phs_tree_extract_resonance_history
```

⟨*PHS trees: procedures*⟩+≡

```
    subroutine phs_tree_extract_resonance_history (tree, res_history)
      class(phs_tree_t), intent(in) :: tree
      type(resonance_history_t), intent(out) :: res_history
      type(resonance_info_t) :: res_info
      integer :: i
      if (allocated (tree%mapping)) then
        do i = 1, size (tree%mapping)
          associate (mapping => tree%mapping(i))
            if (mapping%is_s_channel ()) then
              call res_info%init (mapping%get_bincode (), mapping%get_flv (), &
                   n_out = tree%n_externals - tree%n_in)
              call res_history%add_resonance (res_info)
            end if
          end associate
        end do
      end if
    end subroutine phs_tree_extract_resonance_history
```

Structural comparison

This function allows to check whether one tree is the permutation of another
one. The permutation is applied to the second tree in the argument list. We do
not make up a temporary permuted tree, but compare the two trees directly.
The branches are scanned recursively, where for each daughter we check the
friend and the mapping as well. Once a discrepancy is found, the recursion is
exited immediately.

⟨*PHS trees: public*⟩+≡

```
    public :: phs_tree_equivalent
```

⟨*PHS trees: procedures*⟩+≡

Scan two decay trees and determine the correspondence of mass variables, i.e.,
the permutation that transfers the ordered list of mass variables belonging to
the second tree into the first one. Mass variables are assigned beginning from
branches and ending at the root.

19.7.4   Phase-space evaluation

Phase-space volume

We compute the phase-space volume recursively, following the same path as for computing other kinematical variables. However, the volume depends just on $\sqrt{\hat{s}}$, not on the momentum configuration.

Note: counting branches, we may replace this by a simple formula.

⟨*PHS trees: public*⟩+≡
```
    public :: phs_tree_compute_volume
```

⟨*PHS trees: procedures*⟩+≡
```
    subroutine phs_tree_compute_volume (tree, sqrts, volume)
      type(phs_tree_t), intent(in) :: tree
      real(default), intent(in) :: sqrts
      real(default), intent(out) :: volume
      integer(TC) :: k
      k  = tree%mask_out
      if (tree%branch(k)%has_children) then
         call compute_volume_x (tree%branch(k), k, volume, .true.)
      else
         volume = 1
      end if
    contains
      recursive subroutine compute_volume_x (b, k, volume, initial)
        type(phs_branch_t), intent(in) :: b
```

```
      integer(TC), intent(in) :: k
      real(default), intent(out) :: volume
      logical, intent(in) :: initial
      integer(TC) :: k1, k2
      real(default) :: v1, v2
      k1 = b%daughter(1);  k2 = b%daughter(2)
      if (tree%branch(k1)%has_children) then
         call compute_volume_x (tree%branch(k1), k1, v1, .false.)
      else
         v1 = 1
      end if
      if (tree%branch(k2)%has_children) then
         call compute_volume_x (tree%branch(k2), k2, v2, .false.)
      else
         v2 = 1
      end if
      if (initial) then
         volume = v1 * v2 / (4 * twopi5)
      else
         volume = v1 * v2 * sqrts**2 / (4 * twopi2)
      end if
    end subroutine compute_volume_x
  end subroutine phs_tree_compute_volume
```

Determine momenta

This is done in two steps: First the masses are determined. This step may
fail, in which case `ok` is set to false. If successful, we generate angles and
the actual momenta. The array `decay_p` serves for transferring the individual
three-momenta of the daughter particles in their mother rest frame from the
mass generation to the momentum generation step.

⟨*PHS trees: public*⟩+≡
```
    public :: phs_tree_compute_momenta_from_x
```

⟨*PHS trees: procedures*⟩+≡
```
    subroutine phs_tree_compute_momenta_from_x &
        (tree, prt, factor, volume, sqrts, x, ok)
      type(phs_tree_t), intent(inout) :: tree
      type(phs_prt_t), dimension(:), intent(inout) :: prt
      real(default), intent(out) :: factor, volume
      real(default), intent(in) :: sqrts
      real(default), dimension(:), intent(in) :: x
      logical, intent(out) :: ok
      real(default), dimension(tree%mask_out) :: decay_p
      integer :: n1, n2
      integer :: n_out
      if (tree%real_phsp) then
        n_out = tree%n_externals - tree%n_in - 1
        n1 = max (n_out-2, 0)
        n2 = n1 + max (2*n_out, 0)
      else
        n1 = tree%n_msq
        n2 = n1 + tree%n_angles
```

```
      end if
   call phs_tree_set_msq &
        (tree, prt, factor, volume, decay_p, sqrts, x(1:n1), ok)
   if (ok) call phs_tree_set_angles &
        (tree, prt, factor, decay_p, sqrts, x(n1+1:n2))
end subroutine phs_tree_compute_momenta_from_x
```

Mass generation is done recursively. The `ok` flag causes the filled tree to be discarded if set to `.false.`. This happens if a three-momentum turns out to be imaginary, indicating impossible kinematics. The index `ix` tells us how far we have used up the input array `x`.

⟨*PHS trees: procedures*⟩+≡

The heart of phase space generation: Now we have the invariant masses, let us generate angles. At each branch, we take a Lorentz transformation and augment it by a boost to the current particle rest frame, and by rotations ϕ and θ around the z and y axis, respectively. This transformation is passed down to the daughter particles, if present.

```

This subroutine is the most time-critical part of the whole program. Therefore, we do not exactly parallel the angle generation routine above but make sure that things get evaluated only if they are really needed, at the expense of

readability. Particularly important is to have as few multiplications of Lorentz transformations as possible.

19.8 The phase-space forest

Simply stated, a phase-space forest is a collection of phase-space trees. More precisely, a `phs_forest` object contains all parameterizations of phase space that WHIZARD will use for a single hard process, prepared in the form of `phs_tree` objects. This is suitable for evaluation by the VAMP integration package: each parameterization (tree) is a valid channel in the multi-channel adaptive integration, and each variable in a tree corresponds to an integration dimension, defined by an appropriate mapping of the $(0, 1)$ interval to the allowed range of the integration variable.

The trees are grouped in groves. The trees (integration channels) within a grove share a common weight, assuming that they are related by some approximate symmetry.

Trees/channels that are related by an exact symmetry are connected by an array of equivalences; each equivalence object holds the data that relate one channel to another.

The phase-space setup, i.e., the detailed structure of trees and forest, are read from a file. Therefore, this module also contains the syntax definition and the parser needed for interpreting this file.

19.8.1 Phase-space setup parameters

This transparent container holds the parameters that the algorithm needs for phase-space setup, with reasonable defaults.

The threshold mass (for considering a particle as effectively massless) is specified separately for s- and t-channel. The default is to treat W and Z bosons as massive in the s-channel, but as massless in the t-channel. The b-quark is treated always massless, the t-quark always massive.

⟨*PHS forests: public*⟩≡

```

19.8.2 Equivalences

This type holds information about equivalences between phase-space trees. We make a linked list, where each node contains the two trees which are equivalent and the corresponding permutation of external particles. Two more arrays are to be filled: The permutation of mass variables and the permutation of angular variables, where the signature indicates a necessary exchange of daughter branches.

⟨*PHS forests: types*⟩+≡
```
type :: equivalence_t
   private
   integer :: left, right
   type(permutation_t) :: perm
   type(permutation_t) :: msq_perm, angle_perm
   logical, dimension(:), allocatable :: angle_sig
   type(equivalence_t), pointer :: next => null ()
end type equivalence_t
```

⟨*PHS forests: types*⟩+≡
```
type :: equivalence_list_t
   private
   integer :: length = 0
   type(equivalence_t), pointer :: first => null ()
   type(equivalence_t), pointer :: last => null ()
end type equivalence_list_t
```

Append an equivalence to the list

⟨*PHS forests: procedures*⟩+≡
```
subroutine equivalence_list_add (eql, left, right, perm)
  type(equivalence_list_t), intent(inout) :: eql
  integer, intent(in) :: left, right
  type(permutation_t), intent(in) :: perm
  type(equivalence_t), pointer :: eq
  allocate (eq)
  eq%left = left
  eq%right = right
  eq%perm = perm
  if (associated (eql%last)) then
     eql%last%next => eq
  else
     eql%first => eq
  end if
  eql%last => eq
  eql%length = eql%length + 1
end subroutine equivalence_list_add
```

Delete the list contents. Has to be pure because it is called from an elemental subroutine.

⟨*PHS forests: procedures*⟩+≡
```
pure subroutine equivalence_list_final (eql)
  type(equivalence_list_t), intent(inout) :: eql
  type(equivalence_t), pointer :: eq
```

```
      do while (associated (eql%first))
         eq => eql%first
         eql%first => eql%first%next
         deallocate (eq)
      end do
      eql%last => null ()
      eql%length = 0
   end subroutine equivalence_list_final
```

Make a deep copy of the equivalence list. This allows for deep copies of groves
and forests.

⟨*PHS forests: interfaces*⟩+≡
```
   interface assignment(=)
      module procedure equivalence_list_assign
   end interface
```

⟨*PHS forests: procedures*⟩+≡
```
   subroutine equivalence_list_assign (eql_out, eql_in)
     type(equivalence_list_t), intent(out) :: eql_out
     type(equivalence_list_t), intent(in) :: eql_in
     type(equivalence_t), pointer :: eq, eq_copy
     eq => eql_in%first
     do while (associated (eq))
        allocate (eq_copy)
        eq_copy = eq
        eq_copy%next => null ()
        if (associated (eql_out%first)) then
           eql_out%last%next => eq_copy
        else
           eql_out%first => eq_copy
        end if
        eql_out%last => eq_copy
        eq => eq%next
     end do
   end subroutine equivalence_list_assign
```

The number of list entries
⟨*PHS forests: procedures*⟩+≡
```
   elemental function equivalence_list_length (eql) result (length)
     integer :: length
     type(equivalence_list_t), intent(in) :: eql
     length = eql%length
   end function equivalence_list_length
```

Recursively write the equivalences list
⟨*PHS forests: procedures*⟩+≡
```
   subroutine equivalence_list_write (eql, unit)
     type(equivalence_list_t), intent(in) :: eql
     integer, intent(in), optional :: unit
     integer :: u
     u = given_output_unit (unit);  if (u < 0)  return
     if (associated (eql%first)) then
```

```
            call equivalence_write_rec (eql%first, u)
       else
          write (u, *) " [empty]"
       end if
    contains
      recursive subroutine equivalence_write_rec (eq, u)
        type(equivalence_t), intent(in) :: eq
        integer, intent(in) :: u
        integer :: i
        write (u, "(3x,A,1x,I0,1x,I0,2x,A)", advance="no") &
             "Equivalence:", eq%left, eq%right, "Final state permutation:"
        call permutation_write (eq%perm, u)
        write (u, "(1x,12x,1x,A,1x)", advance="no") &
             "      msq permutation:  "
        call permutation_write (eq%msq_perm, u)
        write (u, "(1x,12x,1x,A,1x)", advance="no") &
             "      angle permutation:"
        call permutation_write (eq%angle_perm, u)
        write (u, "(1x,12x,1x,26x)", advance="no")
        do i = 1, size (eq%angle_sig)
           if (eq%angle_sig(i)) then
              write (u, "(1x,A)", advance="no") "+"
           else
              write (u, "(1x,A)", advance="no") "-"
           end if
        end do
        write (u, *)
        if (associated (eq%next))  call equivalence_write_rec (eq%next, u)
      end subroutine equivalence_write_rec
    end subroutine equivalence_list_write
```

19.8.3   Groves

A grove is a group of trees (phase-space channels) that share a common weight
in the integration. Within a grove, channels can be declared equivalent, so they
also share their integration grids (up to symmetries). The grove contains a list
of equivalences. The tree_count_offset is the total number of trees of the
preceding groves; when the trees are counted per forest (integration channels),
the offset has to be added to all tree indices.

⟨*PHS forests: types*⟩+≡
```
    type :: phs_grove_t
       private
       integer :: tree_count_offset
       type(phs_tree_t), dimension(:), allocatable :: tree
       type(equivalence_list_t) :: equivalence_list
    end type phs_grove_t
```

Call phs_tree_init which is also elemental:

⟨*PHS forests: procedures*⟩+≡
```
    elemental subroutine phs_grove_init &
         (grove, n_trees, n_in, n_out, n_masses, n_angles)
```

```
      type(phs_grove_t), intent(inout) :: grove
      integer, intent(in) :: n_trees, n_in, n_out, n_masses, n_angles
      grove%tree_count_offset = 0
      allocate (grove%tree (n_trees))
      call phs_tree_init (grove%tree, n_in, n_out, n_masses, n_angles)
    end subroutine phs_grove_init
```

The trees do not have pointer components, thus no call to `phs_tree_final`:
⟨*PHS forests: procedures*⟩+≡
```
    elemental subroutine phs_grove_final (grove)
      type(phs_grove_t), intent(inout) :: grove
      deallocate (grove%tree)
      call equivalence_list_final (grove%equivalence_list)
    end subroutine phs_grove_final
```

Deep copy.
⟨*PHS forests: interfaces*⟩+≡
```
    interface assignment(=)
       module procedure phs_grove_assign0
       module procedure phs_grove_assign1
    end interface
```

⟨*PHS forests: procedures*⟩+≡
```
    subroutine phs_grove_assign0 (grove_out, grove_in)
      type(phs_grove_t), intent(out) :: grove_out
      type(phs_grove_t), intent(in) :: grove_in
      grove_out%tree_count_offset = grove_in%tree_count_offset
      if (allocated (grove_in%tree)) then
         allocate (grove_out%tree (size (grove_in%tree)))
         grove_out%tree = grove_in%tree
      end if
      grove_out%equivalence_list = grove_in%equivalence_list
    end subroutine phs_grove_assign0

    subroutine phs_grove_assign1 (grove_out, grove_in)
      type(phs_grove_t), dimension(:), intent(out) :: grove_out
      type(phs_grove_t), dimension(:), intent(in) :: grove_in
      integer :: i
      do i = 1, size (grove_in)
         call phs_grove_assign0 (grove_out(i), grove_in(i))
      end do
    end subroutine phs_grove_assign1
```

Get the global (s-channel) mappings. Implemented as a subroutine which returns an array (slice).
⟨*PHS forests: procedures*⟩+≡
```
    subroutine phs_grove_assign_s_mappings (grove, mapping)
      type(phs_grove_t), intent(in) :: grove
      type(mapping_t), dimension(:), intent(out) :: mapping
      integer :: i
      if (size (mapping) == size (grove%tree)) then
         do i = 1, size (mapping)
```

```
              call phs_tree_assign_s_mapping (grove%tree(i), mapping(i))
          end do
      else
          call msg_bug ("phs_grove_assign_s_mappings: array size mismatch")
      end if
  end subroutine phs_grove_assign_s_mappings
```

19.8.4   The forest type

This is a collection of trees and associated particles. In a given tree, each branch
code corresponds to a particle in the `prt` array. Furthermore, we have an array of
mass sums which is independent of the decay tree and of the particular event.
The mappings directly correspond to the decay trees, and the decay groves
collect the trees in classes. The permutation list consists of all permutations of
outgoing particles that map the decay forest onto itself.

   The particle codes `flv` (one for each external particle) are needed for de-
termining masses and such. The trees and associated information are collected
in the `grove` array, together with a lookup table that associates tree indices to
groves. Finally, the `prt` array serves as workspace for phase-space evaluation.

   The `prt_combination` is a list of index pairs, namely the particle momenta
pairs that need to be combined in order to provide all momentum combinations
that the phase-space trees need to know.

⟨*PHS forests: public*⟩+≡
```
    public :: phs_forest_t
```

⟨*PHS forests: types*⟩+≡
```
    type :: phs_forest_t
       private
       integer :: n_in, n_out, n_tot
       integer :: n_masses, n_angles, n_dimensions
       integer :: n_trees, n_equivalences
       type(flavor_t), dimension(:), allocatable :: flv
       type(phs_grove_t), dimension(:), allocatable :: grove
       integer, dimension(:), allocatable :: grove_lookup
       type(phs_prt_t), dimension(:), allocatable :: prt_in
       type(phs_prt_t), dimension(:), allocatable :: prt_out
       type(phs_prt_t), dimension(:), allocatable :: prt
       integer(TC), dimension(:,:), allocatable :: prt_combination
       type(mapping_t), dimension(:), allocatable :: s_mapping
     contains
     ⟨PHS forests: phs forest: TBP⟩
    end type phs_forest_t
```

The initialization merely allocates memory. We have to know how many trees
there are in each grove, so we can initialize everything. The number of groves
is the size of the **n_tree** array.

   In the `grove_lookup` table we store the grove index that belongs to each
absolute tree index. The difference between the absolute index and the relative
(to the grove) index is stored, for each grove, as `tree_count_offset`.

The particle array is allocated according to the total number of branches each tree has, but not filled.

⟨*PHS forests: public*⟩+≡

```
    public :: phs_forest_init
```

⟨*PHS forests: procedures*⟩+≡

```
    subroutine phs_forest_init (forest, n_tree, n_in, n_out)
      type(phs_forest_t), intent(inout) :: forest
      integer, dimension(:), intent(in) :: n_tree
      integer, intent(in) :: n_in, n_out
      integer :: g, count, k_root
      forest%n_in = n_in
      forest%n_out = n_out
      forest%n_tot = n_in + n_out
      forest%n_masses = max (n_out - 2, 0)
      forest%n_angles = max (2*n_out - 2, 0)
      forest%n_dimensions = forest%n_masses + forest%n_angles
      forest%n_trees = sum (n_tree)
      forest%n_equivalences = 0
      allocate (forest%grove (size (n_tree)))
      call phs_grove_init &
           (forest%grove, n_tree, n_in, n_out, forest%n_masses, &
            forest%n_angles)
      allocate (forest%grove_lookup (forest%n_trees))
      count = 0
      do g = 1, size (forest%grove)
         forest%grove(g)%tree_count_offset = count
         forest%grove_lookup (count+1:count+n_tree(g)) = g
         count = count + n_tree(g)
      end do
      allocate (forest%prt_in  (n_in))
      allocate (forest%prt_out (forest%n_out))
      k_root = 2**forest%n_tot - 1
      allocate (forest%prt (k_root))
      allocate (forest%prt_combination (2, k_root))
      allocate (forest%s_mapping (forest%n_trees))
    end subroutine phs_forest_init
```

Assign the global (s-channel) mappings.

⟨*PHS forests: public*⟩+≡

```
    public :: phs_forest_set_s_mappings
```

⟨*PHS forests: procedures*⟩+≡

```
    subroutine phs_forest_set_s_mappings (forest)
      type(phs_forest_t), intent(inout) :: forest
      integer :: g, i0, i1, n
      do g = 1, size (forest%grove)
         call phs_forest_get_grove_bounds (forest, g, i0, i1, n)
         call phs_grove_assign_s_mappings &
              (forest%grove(g), forest%s_mapping(i0:i1))
      end do
    end subroutine phs_forest_set_s_mappings
```

The grove finalizer is called because it contains the equivalence list:

⟨*PHS forests: public*⟩+≡
```
public :: phs_forest_final
```

⟨*PHS forests: procedures*⟩+≡
```
subroutine phs_forest_final (forest)
  type(phs_forest_t), intent(inout) :: forest
  if (allocated (forest%grove)) then
     call phs_grove_final (forest%grove)
     deallocate (forest%grove)
  end if
  if (allocated (forest%grove_lookup))  deallocate (forest%grove_lookup)
  if (allocated (forest%prt))  deallocate (forest%prt)
  if (allocated (forest%s_mapping))  deallocate (forest%s_mapping)
end subroutine phs_forest_final
```

19.8.5 Screen output

Write the particles that are non-null, then the trees which point to them:

⟨*PHS forests: public*⟩+≡
```
public :: phs_forest_write
```

⟨*PHS forests: phs forest: TBP*⟩≡
```
procedure :: write => phs_forest_write
```

⟨*PHS forests: procedures*⟩+≡
```

19.8.7 Read the phase space setup from file

The phase space setup is stored in a file. The file may be generated by the
`cascades` module below, or by other means. This file has to be read and parsed
to create the PHS forest as the internal phase-space representation.

Create lexer and syntax:

⟨*PHS forests: procedures*⟩+≡

```
   subroutine define_phs_forest_syntax (ifile)
     type(ifile_t) :: ifile
     call ifile_append (ifile, "SEQ phase_space_list = process_phase_space*")
     call ifile_append (ifile, "SEQ process_phase_space = " &
          // "process_def process_header phase_space")
     call ifile_append (ifile, "SEQ process_def = process process_list")
     call ifile_append (ifile, "KEY process")
     call ifile_append (ifile, "LIS process_list = process_tag*")
     call ifile_append (ifile, "IDE process_tag")
     call ifile_append (ifile, "SEQ process_header = " &
          // "md5sum_process = md5sum " &
          // "md5sum_model_par = md5sum " &
          // "md5sum_phs_config = md5sum " &
          // "sqrts = real " &
          // "m_threshold_s = real " &
          // "m_threshold_t = real " &
          // "off_shell = integer " &
          // "t_channel = integer " &
          // "keep_nonresonant = logical")
     call ifile_append (ifile, "KEY '='")
     call ifile_append (ifile, "KEY '-'")
     call ifile_append (ifile, "KEY md5sum_process")
     call ifile_append (ifile, "KEY md5sum_model_par")
     call ifile_append (ifile, "KEY md5sum_phs_config")
     call ifile_append (ifile, "KEY sqrts")
     call ifile_append (ifile, "KEY m_threshold_s")
     call ifile_append (ifile, "KEY m_threshold_t")
     call ifile_append (ifile, "KEY off_shell")
     call ifile_append (ifile, "KEY t_channel")
     call ifile_append (ifile, "KEY keep_nonresonant")
     call ifile_append (ifile, "QUO md5sum = '""' ... '""'")
     call ifile_append (ifile, "REA real")
     call ifile_append (ifile, "INT integer")
     call ifile_append (ifile, "IDE logical")
     call ifile_append (ifile, "SEQ phase_space = grove_def+")
     call ifile_append (ifile, "SEQ grove_def = grove tree_def+")
     call ifile_append (ifile, "KEY grove")
```

2339

```
      call ifile_append (ifile, "SEQ tree_def = tree bincodes mapping*")
      call ifile_append (ifile, "KEY tree")
      call ifile_append (ifile, "SEQ bincodes = bincode*")
      call ifile_append (ifile, "INT bincode")
      call ifile_append (ifile, "SEQ mapping = map bincode channel signed_pdg")
      call ifile_append (ifile, "KEY map")
      call ifile_append (ifile, "ALT channel = &
           &s_channel | t_channel | u_channel | &
           &collinear | infrared | radiation | on_shell")
      call ifile_append (ifile, "KEY s_channel")
      ! call ifile_append (ifile, "KEY t_channel")   !!! Key already exists
      call ifile_append (ifile, "KEY u_channel")
      call ifile_append (ifile, "KEY collinear")
      call ifile_append (ifile, "KEY infrared")
      call ifile_append (ifile, "KEY radiation")
      call ifile_append (ifile, "KEY on_shell")
      call ifile_append (ifile, "ALT signed_pdg = &
           &pdg | negative_pdg")
      call ifile_append (ifile, "SEQ negative_pdg = '-' pdg")
      call ifile_append (ifile, "INT pdg")
    end subroutine define_phs_forest_syntax
```

The model-file syntax and lexer are fixed, therefore stored as module variables:

⟨*PHS forests: variables*⟩≡
```
    type(syntax_t), target, save :: syntax_phs_forest
```

⟨*PHS forests: public*⟩+≡
```
    public :: syntax_phs_forest_init
```

⟨*PHS forests: procedures*⟩+≡
```
    subroutine syntax_phs_forest_init ()
      type(ifile_t) :: ifile
      call define_phs_forest_syntax (ifile)
      call syntax_init (syntax_phs_forest, ifile)
      call ifile_final (ifile)
    end subroutine syntax_phs_forest_init
```

⟨*PHS forests: procedures*⟩+≡
```
    subroutine lexer_init_phs_forest (lexer)
      type(lexer_t), intent(out) :: lexer
      call lexer_init (lexer, &
           comment_chars = "#!", &
           quote_chars = '"', &
           quote_match = '"', &
           single_chars = "-", &
           special_class = ["="] , &
           keyword_list = syntax_get_keyword_list_ptr (syntax_phs_forest))
    end subroutine lexer_init_phs_forest
```

⟨*PHS forests: public*⟩+≡
```
    public :: syntax_phs_forest_final
```

⟨*PHS forests: procedures*⟩+≡

```
    subroutine syntax_phs_forest_final ()
      call syntax_final (syntax_phs_forest)
    end subroutine syntax_phs_forest_final
```

⟨*PHS forests: public*⟩+≡
```
    public :: syntax_phs_forest_write
```

⟨*PHS forests: procedures*⟩+≡
```
    subroutine syntax_phs_forest_write (unit)
      integer, intent(in), optional :: unit
      call syntax_write (syntax_phs_forest, unit)
    end subroutine syntax_phs_forest_write
```

The concrete parser and interpreter. Generate an input stream for the external
`unit`, read the parse tree (with given `syntax` and `lexer`) from this stream, and
transfer the contents of the parse tree to the PHS `forest`.

We look for the matching `process` tag, count groves and trees for initializing
the `forest`, and fill the trees.

If the optional parameters are set, compare the parameters stored in the file
to those. Set `match` true if everything agrees.

⟨*PHS forests: public*⟩+≡

19.8.8 Preparation

The trees that we read from file do not carry flavor information. This is set separately:

The flavor list must be unique for a unique set of masses; if a given particle can have different flavor, the mass must be degenerate, so we can choose one of the possible flavor combinations.

⟨*PHS forests: public*⟩+≡

        end do
      end do
    end subroutine phs_forest_set_momentum_links
```

Once the parameter set is fixed, the masses and the widths of the particles
are known and the `mass_sum` arrays as well as the mapping parameters can be
computed. Note that order is important: we first compute the mass sums, then
the ordinary mappings. The resonances obtained here determine the effective
masses, which in turn are used to implement step mappings for resonance decay
products that are not mapped otherwise.

⟨*PHS forests: public*⟩+≡
```
    public :: phs_forest_set_parameters

          end if
        end do
      end do
    end subroutine phs_forest_set_parameters
```

Generate the particle combination table. Scan all trees and merge their individual combination tables. At the end, valid entries are non-zero, and they indicate the indices of a pair of particles to be combined to a new particle. If a particle is accessible by more than one tree (this is usual), only keep the first possibility.

19.8.10 Find equivalences among phase-space trees

Scan phase space for equivalences. We generate the complete set of unique permutations for the given list of outgoing particles, and use this for scanning equivalences within each grove. We scan all pairs of trees, using all permutations. This implies that trivial equivalences are included, and equivalences between different trees are recorded twice. This is intentional.

⟨PHS forests: procedures⟩+≡
```
    subroutine phs_grove_set_equivalences (grove, perm_array)
      type(phs_grove_t), intent(inout) :: grove
      type(permutation_t), dimension(:), intent(in) :: perm_array

19.8.12   Phase-space evaluation

Given one row of the x parameter array and the corresponding channel index,
compute first all relevant momenta and then recover the remainder of the x
array, the Jacobians phs_factor, and the phase-space volume.

The output argument ok indicates whether this was successful.

⟨*PHS forests: public*⟩+≡
```
    public :: phs_forest_evaluate_selected_channel
```

⟨*PHS forests: procedures*⟩+≡
```
    subroutine phs_forest_evaluate_selected_channel &
        (forest, channel, active, sqrts, x, phs_factor, volume, ok)
      type(phs_forest_t), intent(inout) :: forest

19.9   Finding phase space parameterizations

If the phase space configuration is not found in the appropriate file, we should generate one.

The idea is to construct all Feynman diagrams subject to certain constraints which eliminate everything that is probably irrelevant for the integration. These Feynman diagrams (cascades) are grouped in groves by finding equivalence classes related by symmetry and ordered with respect to their importance (resonances). Finally, the result (or part of it) is written to file and used for the integration.

This module may eventually disappear and be replaced by CAML code. In particular, we need here a set of Feynman rules (vertices with particle codes,

but not the factors). Thus, the module works for the Standard Model only.

Note that this module is stand-alone, it communicates to the main program only via the generated ASCII phase-space configuration file.

19.9.1   The mapping modes

The valid mapping modes, to be used below. We will make use of the convention that mappings of internal particles have a positive value. Only for positive values, the flavor code is propagated when combining cascades.

⟨*Mapping modes*⟩≡
    integer, parameter :: &

```
      & EXTERNAL_PRT = -1, &
      & NO_MAPPING = 0, S_CHANNEL = 1, T_CHANNEL =  2, U_CHANNEL = 3, &
      & RADIATION = 4, COLLINEAR = 5, INFRARED = 6, &
      & STEP_MAPPING_E = 11, STEP_MAPPING_H = 12, &
      & ON_SHELL = 99
```

⟨*Cascades: parameters*⟩≡
  ⟨*Mapping modes*⟩

19.9.2   The cascade type

A cascade is essentially the same as a decay tree (both definitions may be merged in a later version). It contains a linked tree of nodes, each of which representing an internal particle. In contrast to decay trees, each node has a definite particle code. These nodes need not be modified, therefore we can use pointers and do not have to copy them. Thus, physically each cascades has only a single node, the mother particle. However, to be able to compare trees quickly, we store in addition an array of binary codes which is always sorted in ascending order. This is accompanied by a corresponding list of particle codes. The index is the location of the corresponding cascade in the cascade set, this may be used to access the daughters directly.

The real mass is the particle mass belonging to the particle code. The minimal mass is the sum of the real masses of all its daughters; this is the kinematical cutoff. The effective mass may be zero if the particle mass is below a certain threshold; it may be the real mass if the particle is resonant; or it may be some other value.

The logical `t_channel` is set if this a *t*-channel line, while `initial` is true only for an initial particle. Note that both initial particles are also `t_channel` by definition, and that they are distinguished by the direction of the tree: One of them decays and is the root of the tree, while the other one is one of the leaves.

The cascade is a list of nodes (particles) which are linked via the `daughter` entries. The node is the mother particle of the decay cascade. Much of the information in the nodes is repeated in arrays, to be accessible more easily. The arrays will be kept sorted by binary codes.

The counter `n_off_shell` is increased for each internal line that is neither resonant nor log-enhanced. It is set to zero if the current line is resonant, since this implies on-shell particle production and subsequent decay.

The counter `n_t_channel` is non-negative once an initial particle is included in the tree: then, it counts the number of *t*-channel lines.

The `multiplicity` is the number of branchings to follow until all daughters are on-shell. A resonant or non-decaying particle has multiplicity one. Merging nodes, the multiplicities add unless the mother is a resonance. An initial or final node has multiplicity zero.

The arrays correspond to the subnode tree `tree` of the current cascade. PDG codes are stored only for those positions which are resonant, with the exception of the last entry, i.e., the current node. Other positions, in particular external legs, are assigned undefined PDG code.

A cascade is uniquely identified by its tree, the tree of PDG codes, and the tree of mappings. The tree of resonances is kept only to mask the PDG tree as

2362

described above.

   ! next in list
   type(cascade_t), pointer :: next => null ()
 contains
 ⟨Cascades: cascade: TBP⟩
end type cascade_t
```

⟨*Cascades: procedures*⟩≡

```
subroutine cascade_init (cascade, depth)
  type(cascade_t), intent(out) :: cascade
  integer, intent(in) :: depth
  integer, save :: index = 0
```

2363

```
    index = cascade_index ()
    cascade%index = index
    cascade%depth = depth
    cascade%active = .true.
    allocate (cascade%tree (depth))
    allocate (cascade%tree_pdg (depth))
    allocate (cascade%tree_mapping (depth))
    allocate (cascade%tree_resonant (depth))
  end subroutine cascade_init
```

Keep and increment a global index

⟨*Cascades: procedures*⟩+≡
```
    function cascade_index (seed) result (index)
      integer :: index
      integer, intent(in), optional :: seed
      integer, save :: i = 0
      if (present (seed))  i = seed
      i = i + 1
      index = i
    end function cascade_index
```

We need three versions of writing cascades. This goes to the phase-space file.

For t/u channel mappings, we use the absolute value of the PDG code.

19.9.3   Creating new cascades

This initializes a single-particle cascade (external, final state). The PDG entry
in the tree is set undefined because the cascade is not resonant. However, the
flavor entry is set, so the cascade flavor is identified nevertheless.

⟨*Cascades: procedures*⟩+≡
```
    subroutine cascade_init_outgoing (cascade, flv, pos, m_thr)
      type(cascade_t), intent(out) :: cascade
      type(flavor_t), intent(in) :: flv
      integer, intent(in) :: pos
      real(default), intent(in) :: m_thr
      call cascade_init (cascade, 1)
      cascade%bincode = ibset (0_TC, pos-1)
      cascade%flv = flv
      cascade%pdg = cascade%flv%get_pdg ()
      cascade%is_vector = flv%get_spin_type () == VECTOR
      cascade%m_min = flv%get_mass ()
      cascade%m_rea = cascade%m_min
      if (cascade%m_rea >= m_thr) then
         cascade%m_eff = cascade%m_rea
      end if
      cascade%on_shell = .true.
      cascade%multiplicity = 1
      cascade%tree(1) = cascade%bincode
      cascade%tree_pdg(1) = cascade%pdg
      cascade%tree_mapping(1) = EXTERNAL_PRT
      cascade%tree_resonant(1) = .false.
    end subroutine cascade_init_outgoing
```

The same for an incoming line:

⟨*Cascades: procedures*⟩+≡
```
    subroutine cascade_init_incoming (cascade, flv, pos, m_thr)
      type(cascade_t), intent(out) :: cascade
```

```
    type(flavor_t), intent(in) :: flv
    integer, intent(in) :: pos

    cascade%tree_resonant(1) = .false.
  end subroutine cascade_init_incoming
```

19.9.4   Tools

This function returns true if the two cascades share no common external particle.
This is a requirement for joining them.

⟨*Cascades: interfaces*⟩≡
```
    interface operator(.disjunct.)
       module procedure cascade_disjunct
    end interface
```

⟨*Cascades: procedures*⟩+≡
```
    function cascade_disjunct (cascade1, cascade2) result (flag)
      logical :: flag
      type(cascade_t), intent(in) :: cascade1, cascade2
      flag = iand (cascade1%bincode, cascade2%bincode) == 0
    end function cascade_disjunct
```

Compute a hash code for the resonance pattern of a cascade. We count the
number of times each particle appears as a resonance.

We pack the PDG codes of the resonances in two arrays (s-channel and t-
channel), sort them both, concatenate the results, transfer to `i8` integers, and
compute the hash code from this byte stream.

For t/u-channel, we remove the sign for antiparticles since this is not well-
defined.

⟨*Cascades: procedures*⟩+≡
```
    subroutine cascade_assign_resonance_hash (cascade)
      type(cascade_t), intent(inout) :: cascade
      integer(i8), dimension(1) :: mold
      cascade%res_hash = hash (transfer &
```

```
          ([sort (pack (cascade%tree_pdg, &
                 cascade%tree_resonant)), &
            sort (pack (abs (cascade%tree_pdg), &
                 cascade%tree_mapping == T_CHANNEL .or. &
                 cascade%tree_mapping == U_CHANNEL))], &
          mold))
    end subroutine cascade_assign_resonance_hash
```

19.9.5 Hash entries for cascades

We will set up a hash array which contains keys of and pointers to cascades.
We hold a list of cascade (pointers) within each bucket. This is not for collision
resolution, but for keeping similar, but unequal cascades together.

⟨*Cascades: types*⟩+≡
```
    type :: cascade_p
      type(cascade_t), pointer :: cascade => null ()
      type(cascade_p), pointer :: next => null ()
    end type cascade_p
```

Here is the bucket or hash entry type:

⟨*Cascades: types*⟩+≡
```
    type :: hash_entry_t
      integer(i32) :: hashval = 0
      integer(i8), dimension(:), allocatable :: key
      type(cascade_p), pointer :: first => null ()
      type(cascade_p), pointer :: last => null ()
    end type hash_entry_t
```

⟨*Cascades: public*⟩≡
```
    public :: hash_entry_init
```

⟨*Cascades: procedures*⟩+≡
```
    subroutine hash_entry_init (entry, entry_in)
      type(hash_entry_t), intent(out) :: entry
      type(hash_entry_t), intent(in) :: entry_in
      type(cascade_p), pointer :: casc_iter, casc_copy
      entry%hashval = entry_in%hashval
      entry%key = entry_in%key
      casc_iter => entry_in%first
      do while (associated (casc_iter))
         allocate (casc_copy)
         casc_copy = casc_iter
         casc_copy%next => null ()
         if (associated (entry%first)) then
            entry%last%next => casc_copy
         else
            entry%first => casc_copy
         end if
         entry%last => casc_copy
         casc_iter => casc_iter%next
      end do
    end subroutine hash_entry_init
```

Finalize: just deallocate the list; the contents are just pointers.

⟨*Cascades: procedures*⟩+≡
```
subroutine hash_entry_final (hash_entry)
  type(hash_entry_t), intent(inout) :: hash_entry
  type(cascade_p), pointer :: current
  do while (associated (hash_entry%first))
     current => hash_entry%first
     hash_entry%first => current%next
     deallocate (current)
  end do
end subroutine hash_entry_final
```

Output: concise format for debugging, just list cascade indices.

⟨*Cascades: procedures*⟩+≡
```
subroutine hash_entry_write (hash_entry, unit)
  type(hash_entry_t), intent(in) :: hash_entry
  integer, intent(in), optional :: unit
  type(cascade_p), pointer :: current
  integer :: u, i
  u = given_output_unit (unit);  if (u < 0)  return
  write (u, "(1x,A)", advance="no")  "Entry:"
  do i = 1, size (hash_entry%key)
     write (u, "(1x,I0)", advance="no")  hash_entry%key(i)
  end do
  write (u, "(1x,A)", advance="no")  "->"
  current => hash_entry%first
  do while (associated (current))
     write (u, "(1x,I7)", advance="no") current%cascade%index
     current => current%next
  end do
  write (u, *)
end subroutine hash_entry_write
```

This function adds a cascade pointer to the bucket. If `ok` is present, check first
if it is already there and return failure if yes. If `cascade_ptr` is also present,
set it to the current cascade if successful. If not, set it to the cascade that is
already there.

⟨*Cascades: procedures*⟩+≡
```
subroutine hash_entry_add_cascade_ptr (hash_entry, cascade, ok, cascade_ptr)
  type(hash_entry_t), intent(inout) :: hash_entry
  type(cascade_t), intent(in), target :: cascade
  logical, intent(out), optional :: ok
  type(cascade_t), optional, pointer :: cascade_ptr
  type(cascade_p), pointer :: current
  if (present (ok)) then
     call hash_entry_check_cascade (hash_entry, cascade, ok, cascade_ptr)
     if (.not. ok)  return
  end if
  allocate (current)
  current%cascade => cascade
  if (associated (hash_entry%last)) then
```

```
          hash_entry%last%next => current
      else
          hash_entry%first => current
      end if
      hash_entry%last => current
   end subroutine hash_entry_add_cascade_ptr
```

This function checks whether a cascade is already in the bucket. For incomplete cascades, we look for an exact match. It should suffice to verify the tree, the PDG codes, and the mapping modes. This is the information that is written to the phase space file.

For complete cascades, we ignore the PDG code at positions with mappings infrared, collinear, or t/u-channel. Thus a cascade which is distinguished only by PDG code at such places, is flagged existent. If the convention is followed that light particles come before heavier ones (in the model definition), this ensures that the lightest particle is kept in the appropriate place, corresponding to the strongest peak.

For external cascades (incoming/outgoing) we take the PDG code into account even though it is zeroed in the PDG-code tree.

⟨Cascades: procedures⟩+≡
```
   subroutine hash_entry_check_cascade (hash_entry, cascade, ok, cascade_ptr)
     type(hash_entry_t), intent(in), target :: hash_entry
     type(cascade_t), intent(in), target :: cascade
     logical, intent(out) :: ok
     type(cascade_t), optional, pointer :: cascade_ptr
     type(cascade_p), pointer :: current
     integer, dimension(:), allocatable :: tree_pdg
     ok = .true.
     allocate (tree_pdg (size (cascade%tree_pdg)))
     if (cascade%complete) then
        where (cascade%tree_mapping == INFRARED .or. &
               cascade%tree_mapping == COLLINEAR .or. &
               cascade%tree_mapping == T_CHANNEL .or. &
               cascade%tree_mapping == U_CHANNEL)
           tree_pdg = 0
        elsewhere
           tree_pdg = cascade%tree_pdg
        end where
     else
        tree_pdg = cascade%tree_pdg
     end if
     current => hash_entry%first
     do while (associated (current))
        if (current%cascade%depth == cascade%depth) then
           if (all (current%cascade%tree == cascade%tree)) then
              if (all (current%cascade%tree_mapping == cascade%tree_mapping)) &
                   then
                 if (all (current%cascade%tree_pdg .match. tree_pdg)) then
                    if (present (cascade_ptr))  cascade_ptr => current%cascade
                    ok = .false.;  return
                 end if
              end if
           end if
```

2373

```
        end if
        current => current%next
      end do
      if (present (cascade_ptr))  cascade_ptr => cascade
    end subroutine hash_entry_check_cascade
```

For PDG codes, we specify that the undefined code matches any code. This is
already defined for flavor objects, but here we need it for the codes themselves.

⟨*Cascades: interfaces*⟩+≡
```
    interface operator(.match.)
       module procedure pdg_match
    end interface
```

⟨*Cascades: procedures*⟩+≡
```
    elemental function pdg_match (pdg1, pdg2) result (flag)
      logical :: flag
      integer(TC), intent(in) :: pdg1, pdg2
      select case (pdg1)
      case (0)
         flag = .true.
      case default
         select case (pdg2)
         case (0)
            flag = .true.
         case default
            flag = pdg1 == pdg2
         end select
      end select
    end function pdg_match
```

19.9.6   The cascade set

The cascade set will later be transformed into the decay forest. It is set up as a
linked list. In addition to the usual `first` and `last` pointers, there is a `first_t`
pointer which points to the first t-channel cascade (after all s-channel cascades),
and a `first_k` pointer which points to the first final cascade (with a keystone).

As an auxiliary device, the object contains a hash array with associated
parameters where an additional pointer is stored for each cascade. The keys are
made from the relevant cascade data. This hash is used for fast detection (and
thus avoidance) of double entries in the cascade list.

⟨*Cascades: public*⟩+≡
```
    public :: cascade_set_t
```

⟨*Cascades: types*⟩+≡
```
    type :: cascade_set_t
      private

         end if
         cascade => cascade%next
      end do
    end function cascade_set_is_valid
```

The initializer sets up the hash table with some initial size guessed by looking at the number of external particles. We choose 256 for 3 external particles and a factor of 4 for each additional particle, limited at 2^{30}=1G.

Note: the explicit initialization loop might be avoided (ELEMENTAL), but a bug in nagfor 5.3.2 prevents this.

⟨*Cascades: parameters*⟩+≡

19.9.7   Adding cascades

Add a deep copy of a cascade to the set. The copy has all content of the original,
but the pointers are nullified. We do not care whether insertion was successful
or not. The pointer argument, if present, is assigned to the input cascade, or to
the hash entry if it is already present.

The procedure is recursive: any daughter or mother entries are also deep-
copied and added to the cascade set before the current copy is added.

⟨*Cascades: procedures*⟩+≡
```
   recursive subroutine cascade_set_add_copy &
       (cascade_set, cascade_in, cascade_ptr)
     type(cascade_set_t), intent(inout), target :: cascade_set
     type(cascade_t), intent(in) :: cascade_in
     type(cascade_t), optional, pointer :: cascade_ptr
     type(cascade_t), pointer :: cascade
     logical :: ok
     allocate (cascade)
     cascade = cascade_in
     if (associated (cascade_in%daughter1))  call cascade_set_add_copy &
         (cascade_set, cascade_in%daughter1, cascade%daughter1)
     if (associated (cascade_in%daughter2))  call cascade_set_add_copy &
         (cascade_set, cascade_in%daughter2, cascade%daughter2)
     if (associated (cascade_in%mother))  call cascade_set_add_copy &
         (cascade_set, cascade_in%mother, cascade%mother)
     cascade%next => null ()
     call cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
     if (.not. ok)  deallocate (cascade)
   end subroutine cascade_set_add_copy
```

Add a cascade to the set. This does not deep-copy. We first try to insert it
in the hash array. If successful, add it to the list. Failure indicates that it is
already present, and we drop it.

The hash key is built solely from the tree array, so neither particle codes nor
resonances count, just topology.

Technically, hash and list receive only pointers, so the cascade can be con-
sidered as being in either of both. We treat it as part of the list.

⟨*Cascades: procedures*⟩+≡
```
   subroutine cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
```

```
      type(cascade_set_t), intent(inout), target :: cascade_set
      type(cascade_t), intent(in), target :: cascade
      logical, intent(out) :: ok
      type(cascade_t), optional, pointer :: cascade_ptr
      integer(i8), dimension(1) :: mold
      call cascade_set_hash_insert &
           (cascade_set, transfer (cascade%tree, mold), cascade, ok, cascade_ptr)
      if (ok)  call cascade_set_list_add (cascade_set, cascade)
    end subroutine cascade_set_add
```

Add a new cascade to the list:

⟨*Cascades: procedures*⟩+≡
```
    subroutine cascade_set_list_add (cascade_set, cascade)
      type(cascade_set_t), intent(inout) :: cascade_set
      type(cascade_t), intent(in), target :: cascade
      if (associated (cascade_set%last)) then
         cascade_set%last%next => cascade
      else
         cascade_set%first => cascade
      end if
      cascade_set%last => cascade
    end subroutine cascade_set_list_add
```

Add a cascade entry to the hash array:

⟨*Cascades: procedures*⟩+≡
```
    subroutine cascade_set_hash_insert &
         (cascade_set, key, cascade, ok, cascade_ptr)
      type(cascade_set_t), intent(inout), target :: cascade_set
      integer(i8), dimension(:), intent(in) :: key
      type(cascade_t), intent(in), target :: cascade
      logical, intent(out) :: ok
      type(cascade_t), optional, pointer :: cascade_ptr
      integer(i32) :: h
      if (cascade_set%n_entries >= cascade_set%n_entries_max) &
           call cascade_set_hash_expand (cascade_set)
      h = hash (key)
      call cascade_set_hash_insert_rec &
           (cascade_set, h, h, key, cascade, ok, cascade_ptr)
    end subroutine cascade_set_hash_insert
```

Double the hashtable size when necesssary:

⟨*Cascades: procedures*⟩+≡
```
    subroutine cascade_set_hash_expand (cascade_set)
      type(cascade_set_t), intent(inout), target :: cascade_set
      type(hash_entry_t), dimension(:), allocatable, target :: table_tmp
      type(cascade_p), pointer :: current
      integer :: i, s
      allocate (table_tmp (0:cascade_set%mask))
      table_tmp = cascade_set%entry
      deallocate (cascade_set%entry)
      s = 2 * size (table_tmp)
      cascade_set%n_entries = 0
```

```
      cascade_set%n_entries_max = s * cascade_set%fill_ratio
      cascade_set%mask = s - 1
      allocate (cascade_set%entry (0:cascade_set%mask))
      do i = 0, ubound (table_tmp, 1)
         current => table_tmp(i)%first
         do while (associated (current))
            call cascade_set_hash_insert_rec &
                 (cascade_set, table_tmp(i)%hashval, table_tmp(i)%hashval, &

```

Insert the cascade at the bucket determined by the hash value. If the bucket is filled, check first for a collision (unequal keys). In that case, choose the following bucket and repeat. Otherwise, add the cascade to the bucket.

If the bucket is empty, record the hash value, allocate and store the key, and then add the cascade to the bucket.

If ok is present, before insertion we check whether the cascade is already stored, and return failure if yes.

```

19.9.9   Cascade combination I: flavor assignment

We have two disjunct cascades, now use the vertex table to determine the possible flavors of the combination cascade. For each possibility, try to generate a new cascade. The total cascade depth has to be one less than the limit, because this is reached by setting the keystone.

⟨*Cascades: procedures*⟩+≡
```
    subroutine cascade_match_pair (cascade_set, cascade1, cascade2, s_channel)
      type(cascade_set_t), intent(inout), target :: cascade_set
      type(cascade_t), intent(in), target :: cascade1, cascade2
      logical, intent(in) :: s_channel
      integer, dimension(:), allocatable :: pdg3
      integer :: i, depth_max
      type(flavor_t) :: flv
      if (s_channel) then
          depth_max = cascade_set%depth_out
      else
          depth_max = cascade_set%depth_tot
      end if
      if (cascade1%depth + cascade2%depth < depth_max) then
          call cascade_set%model%match_vertex ( &
               cascade1%flv%get_pdg (), &
               cascade2%flv%get_pdg (), &
               pdg3)
          do i = 1, size (pdg3)
             call flv%init (pdg3(i), cascade_set%model)
             if (s_channel) then
                call cascade_combine_s (cascade_set, cascade1, cascade2, flv)
             else
                call cascade_combine_t (cascade_set, cascade1, cascade2, flv)
             end if
          end do
          deallocate (pdg3)
      end if
    end subroutine cascade_match_pair
```

The triplet version takes a third cascade, and we check whether this triplet has a matching vertex in the database. If yes, we make a keystone cascade.

⟨*Cascades: procedures*⟩+≡
```
    subroutine cascade_match_triplet &
         (cascade_set, cascade1, cascade2, cascade3, s_channel)
      type(cascade_set_t), intent(inout), target :: cascade_set
```

```
      type(cascade_t), intent(in), target :: cascade1, cascade2, cascade3
      logical, intent(in) :: s_channel
      integer :: depth_max
      depth_max = cascade_set%depth_tot
      if (cascade1%depth + cascade2%depth + cascade3%depth == depth_max) then
         if (cascade_set%model%check_vertex ( &
               cascade1%flv%get_pdg (), &
               cascade2%flv%get_pdg (), &
               cascade3%flv%get_pdg ())) then
            call cascade_combine_keystone &
                  (cascade_set, cascade1, cascade2, cascade3, s_channel)
         end if
      end if
    end subroutine cascade_match_triplet
```

19.9.10 Cascade combination II: kinematics setup and check

Having three matching flavors, we start constructing the combination cascade.
We look at the mass hierarchies and determine whether the cascade is to be
kept. In passing we set mapping modes, resonance properties and such.

   If successful, the cascade is finalized. For a resonant cascade, we prepare in
addition a copy without the resonance.

⟨*Cascades: procedures*⟩+≡

```
    subroutine cascade_combine_s (cascade_set, cascade1, cascade2, flv)

```

Here we complete a decay cascade. The third input is the single-particle cascade for the initial particle. There is no resonance or mapping assignment. The only condition for keeping the cascade is the mass sum of the final state, which must be less than the available energy.

Two modifications are necessary for scattering cascades: a pure s-channel diagram (cascade1 is the incoming particle) do not have a logarithmic mapping at top-level. And in a t-channel diagram, the last line exchanged is mapped t-channel, not u-channel. Finally, we can encounter the case of a $2 \to 1$ process, where cascade1 is incoming, and cascade2 is the outgoing particle. In all three cases we register a new cascade with the modified mapping.

⟨*Cascades: procedures*⟩+≡
```
    subroutine cascade_combine_keystone &
        (cascade_set, cascade1, cascade2, cascade3, s_channel)

19.9.11 Cascade combination III: node connections and tree fusion

Here we assign global tree properties. If the allowed number of off-shell lines is exceeded, discard the new cascade. Otherwise, assign the trees, sort them, and assign connections. Finally, append the cascade to the list. This may fail (because in the hash array there is already an equivalent cascade). On failure, discard the cascade.

⟨*Cascades: procedures*⟩+≡
```
   subroutine cascade_fusion (cascade_set, cascade1, cascade2, cascade3)
     type(cascade_set_t), intent(inout), target :: cascade_set
     type(cascade_t), intent(in), target :: cascade1, cascade2

           end if
       end if
    end if
  end subroutine cascade_keystone
```

Sort a tree (array of binary codes) and particle code array simultaneously, by ascending binary codes. A convenient method is to use the `maxloc` function iteratively, to find and remove the largest entry in the tree array one by one.

⟨*Cascades: procedures*⟩+≡

```
    subroutine tree_sort (tree, pdg, mapping, resonant)
      integer(TC), dimension(:), intent(inout) :: tree
      integer, dimension(:), intent(inout) :: pdg, mapping
      logical, dimension(:), intent(inout) :: resonant
      integer(TC), dimension(size(tree)) :: tree_tmp
```

```
      integer, dimension(size(pdg)) :: pdg_tmp, mapping_tmp
      logical, dimension(size(resonant)) :: resonant_tmp
      integer, dimension(1) :: pos
      integer :: i
      tree_tmp = tree
      pdg_tmp = pdg
      mapping_tmp = mapping
      resonant_tmp = resonant
      do i = size(tree),1,-1
         pos = maxloc (tree_tmp)
         tree(i) = tree_tmp (pos(1))
         pdg(i) = pdg_tmp (pos(1))
         mapping(i) = mapping_tmp (pos(1))
         resonant(i) = resonant_tmp (pos(1))
         tree_tmp(pos(1)) = 0
      end do
   end subroutine tree_sort
```

19.9.12   Cascade set generation

These procedures loop over cascades and build up the cascade set. After each
iteration of the innermost loop, we set a breakpoint.

s-channel: We use a nested scan to combine all cascades with all other
cascades.

⟨*Cascades: procedures*⟩+≡
```
   subroutine cascade_set_generate_s (cascade_set)
     type(cascade_set_t), intent(inout), target :: cascade_set
     type(cascade_t), pointer :: cascade1, cascade2
     cascade1 => cascade_set%first
     LOOP1: do while (associated (cascade1))
        cascade2 => cascade_set%first
        LOOP2: do while (associated (cascade2))
           if (cascade2%index >= cascade1%index)  exit LOOP2
           if (cascade1 .disjunct. cascade2) then
              call cascade_match_pair (cascade_set, cascade1, cascade2, .true.)
           end if
           call terminate_now_if_signal ()
           cascade2 => cascade2%next
        end do LOOP2
        cascade1 => cascade1%next
     end do LOOP1
   end subroutine cascade_set_generate_s
```

The t-channel cascades are directed and have a seed (one of the incoming parti-
cles) and a target (the other one). We loop over all possible seeds and targets.
Inside this, we loop over all t-channel cascades (`cascade1`) and s-channel cas-
cades (`cascade2`) and try to combine them.

⟨*Cascades: procedures*⟩+≡
```
   subroutine cascade_set_generate_t (cascade_set, pos_seed, pos_target)
     type(cascade_set_t), intent(inout), target :: cascade_set
     integer, intent(in) :: pos_seed, pos_target
```

```
      type(cascade_t), pointer :: cascade_seed, cascade_target

19.9.13 Groves

Before assigning groves, assign hashcodes to the resonance patterns, so they can easily be compared.

⟨*Cascades: procedures*⟩+≡
```
subroutine cascade_set_assign_resonance_hash (cascade_set)
  type(cascade_set_t), intent(inout) :: cascade_set
  type(cascade_t), pointer :: cascade
  cascade => cascade_set%first_k
  do while (associated (cascade))
     call cascade_assign_resonance_hash (cascade)
     cascade => cascade%next
  end do
end subroutine cascade_set_assign_resonance_hash
```

After all cascades are recorded, we group the complete cascades in groves. A grove consists of cascades with identical multiplicity, number of resonances, log-enhanced, t-channel lines, and resonance flavors.

⟨*Cascades: procedures*⟩+≡
```
subroutine cascade_set_assign_groves (cascade_set)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), pointer :: cascade1, cascade2
  integer :: multiplicity
  integer :: n_resonances, n_log_enhanced, n_t_channel, n_off_shell
  integer :: res_hash
  integer :: grove
  grove = 0
  cascade1 => cascade_set%first_k
  do while (associated (cascade1))
     if (cascade1%active .and. cascade1%complete &
          .and. cascade1%grove == 0) then
        grove = grove + 1
        cascade1%grove = grove
```

```
         multiplicity = cascade1%multiplicity
         n_resonances = cascade1%n_resonances
         n_log_enhanced = cascade1%n_log_enhanced
         n_off_shell = cascade1%n_off_shell
         n_t_channel = cascade1%n_t_channel
         res_hash = cascade1%res_hash
         cascade2 => cascade1%next
         do while (associated (cascade2))
            if (cascade2%grove == 0) then
               if (cascade2%multiplicity == multiplicity &
                    .and. cascade2%n_resonances == n_resonances &
                    .and. cascade2%n_log_enhanced == n_log_enhanced &
                    .and. cascade2%n_off_shell == n_off_shell &
                    .and. cascade2%n_t_channel == n_t_channel &
                    .and. cascade2%res_hash == res_hash) then
                  cascade2%grove = grove
               end if
            end if
            call terminate_now_if_signal ()
            cascade2 => cascade2%next
         end do
      end if
      call terminate_now_if_signal ()
      cascade1 => cascade1%next
   end do
   cascade_set%n_groves = grove
 end subroutine cascade_set_assign_groves
```

19.9.14 Generate the phase space file

Generate a complete phase space configuration.

For each flavor assignment: First, all s-channel graphs that can be built up from the outgoing particles. Then we distinguish (1) decay, where we complete the s-channel graphs by connecting to the input line, and (2) scattering, where we now generate t-channel graphs by introducing an incoming particle, and complete this by connecting to the other incoming particle.

After all cascade sets have been generated, merge them into a common set. This eliminates redunancies between flavor assignments.

⟨*Cascades: public*⟩+≡
```
   public :: cascade_set_generate
```

⟨*Cascades: procedures*⟩+≡
```
   subroutine cascade_set_generate &
       (cascade_set, model, n_in, n_out, flv, phs_par, fatal_beam_decay)
     type(cascade_set_t), intent(out) :: cascade_set
     class(model_data_t), intent(in), target :: model
     integer, intent(in) :: n_in, n_out
     type(flavor_t), dimension(:,:), intent(in) :: flv
     type(phs_parameters_t), intent(in) :: phs_par
     logical, intent(in) :: fatal_beam_decay
     type(cascade_set_t), dimension(:), allocatable :: cset
     type(cascade_t), pointer :: cascade
```

```
      integer :: i
      if (phase_space_vanishes (phs_par%sqrts, n_in, flv))  return
      call cascade_set_init (cascade_set, model, n_in, n_out, phs_par, &
         fatal_beam_decay, flv)
      allocate (cset (size (flv, 2)))
      do i = 1, size (cset)
         call cascade_set_generate_single (cset(i), &
              model, n_in, n_out, flv(:,i), phs_par, fatal_beam_decay)
         cascade => cset(i)%first_k
         do while (associated (cascade))
            if (cascade%active .and. cascade%complete) then
               call cascade_set_add_copy (cascade_set, cascade)
            end if
            cascade => cascade%next
         end do
         call cascade_set_final (cset(i))
      end do
      cascade_set%first_k => cascade_set%first
      call cascade_set_assign_resonance_hash (cascade_set)
      call cascade_set_assign_groves (cascade_set)
   end subroutine cascade_set_generate
```

This generates phase space for a single channel, without assigning groves.

19.10 WOOD phase space

This is the module that interfaces the `phs_forests` phase-space treatment and
the `cascades` module for generating phase-space channels. As an extension of
the `phs_base` abstract type, the phase-space configuration and instance imple-
ment the standard API.

(Currently, this is the only generic phase-space implementation of WHIZARD. For trivial two-particle phase space, there is phs_wood as an alternative.)

19.10.3   Phase-space configuration

We read the phase-space configuration from the stored I/O unit. If this is not set, we assume that we have to generate a phase space configuration. When done, we open a scratch file and write the configuration.

If `rebuild` is set, we should trash any existing phase space file and build a new one. Otherwise, we try to use an old one, which we check for existence and integrity. If `ignore_mismatch` is set, we reuse an existing file even if it does not match the current setup.

⟨*PHS wood: phs wood config: TBP*⟩+≡
```
   procedure :: configure => phs_wood_config_configure
```

⟨*PHS wood: procedures*⟩+≡

```

The MD5 sum of the forest is computed in addition to the MD5 sum of the
configuration. The reason is that the forest may depend on a user-provided
external file. On the other hand, this MD5 sum encodes all information that is
relevant for further processing. Therefore, the `get_md5sum` method returns this
result, once it is available.

```

Create filenames according to standard conventions. The `id` is the process name
including the suffix `_iX` where `X` stands for the component identifier (an integer).
The `run_id` may be set or unset.

   The convention for file names that include the run ID is to separate prefix,
run ID, and any extensions by dots. We construct the file name by concatenating
the individual elements accordingly. If there is no run ID, we nevertheless replace
`_iX` by `.iX`.

     end subroutine phs_wood_init
```

19.10.5   Evaluation

We compute the outgoing momenta from the incoming momenta and the input
parameter set r_in in channel r_in. We also compute the r parameters and
Jacobians f for all other channels.

   We do *not* need to a apply a transformation from/to the c.m. frame, because
in **phs_base** the momenta are already boosted to the c.m. frame before assigning
them in the **phs** object, and inversely boosted when extracting them.

The boost to the center-of-mass system only has a reasonable meaning above
the threshold. Below the threshold, we do not apply boost at all, so that
the top quarks stay in the rest frame. However, with top quarks exactly at
rest, problems arise in the matrix elements (e.g. in the computation of angles).
Therefore, we apply a boost which is not exactly 1, but has a tiny value differing
from that.

A resonance phase space is uniquely specified via the resonance contributors and the corresponding emitters. The `phs_identifier` type also checks whether the given contributor-emitter configuration has already been evaluated to avoid duplicate computations.

The fks phase space type contains the wood phase space and separately the in- and outcoming momenta for the real process and the corresponding Born momenta. Additionally, there are the variables ξ, ξ_{max}, y and ϕ which are used to create the real phase space, as well as the jacobian and its corresponding soft

and collinear limit. Lastly, the array `ch_to_em` connects each channel with an emitter.

19.11.1   Creation of the real phase space - FSR

At this point, the Born phase space has been generated, as well as the three random variables ξ, y and ϕ. The question is how the real phase space is generated for a final-state emission configuration. We work with two different sets of momenta, the Born configuration $\left\{\bar{k}_\oplus, \bar{k}_\ominus, \bar{k}_1, ..., \bar{k}_n\right\}$ and the real configuration $\left\{k_\oplus, k_\ominus, k_1, ..., k_n, k_{n+1}\right\}$. We define the momentum of the emitter to be on the n-th position and the momentum of the radiated particle to be at position $n+1$. The magnitude of the spatial component of k is denoted by $\underline{k}$.

For final-state emissions, it is $\bar{k}_\oplus = k_\oplus$ and $\bar{k}_\ominus = k_\ominus$. Thus, the center-of-mass systems coincide and it is

$$q = \sum_{i=1}^{n} \bar{k}_i = \sum_{i=1}^{n+1} k_i, \tag{19.65}$$

with $\vec{q} = 0$ and $q^2 = \left(q^0\right)^2$.

We want to construct the real phase space from the Born phase space using three random numbers. They are defined as follows:

- $\xi = \frac{2k_{n+1}^0}{\sqrt{s}} \in [0, \xi_{max}]$, where k_{n+1} denotes the four-momentum of the radiated particle.

- $y = \cos\theta = \frac{\vec{k}_n \cdot \vec{k}_{n+1}}{\underline{k}_n \underline{k}_{n+1}}$ is the splitting angle.

- The angle between tho two splitting particles in the transversal plane, $phi \in [0, 2\pi]$.

Further, $k_{rec} = \sum_{i=1}^{n-1} k_i$ denotes the sum of all recoiling momenta.

Construction of the recoiling momenta. The reshuffling of momenta must not change the invariant mass of the recoiling system, which means $k_{\mathrm{rec}}^2 = \bar{k}_{\mathrm{rec}}^{\,2}$. Therefore, the momenta are related by a boost, $\bar{k}_i = \Lambda k_i$. The boost parameter is

$$\beta = \frac{q^2 - (k_{\mathrm{rec}}^0 + \underline{k}_{\mathrm{rec}})^2}{q^2 + (k_{\mathrm{rec}}^0 + \underline{k}_{\mathrm{rec}})^2}$$

The momentum of the radiated particle is computed according to

$$\underline{k}_n = \frac{q^2 - M_{\text{rec}}^2 - 2q^0\underline{k}_{n+1}}{2(q^0 - \underline{k}_{n+1}(1 - y))}, \tag{19.66}$$

with $k = k_n + k_{n+1}$ and $M_{\text{rec}}^2 = k_{\text{rec}}^2 = (q - k)^2$. Because of $\bar{\boldsymbol{k}}_n \parallel \boldsymbol{k}_n + \boldsymbol{k}_{n+1}$ we find $M_{\text{rec}}^2 = (q - \bar{k}_n)^2$. Equation **??** follows from the fact that $(\boldsymbol{k} - \boldsymbol{k}_n)^2 = \boldsymbol{k}_{n+1}^2$, which is equivalent to $\boldsymbol{k}_n \cdot \boldsymbol{k} = \frac{1}{2}(\underline{k}_n^2 + \underline{k}^2 - \underline{k}_{n+1}^2)$.
$\boldsymbol{k}_n$ and $\boldsymbol{k}_{n+1}$ are obtained by first setting up vectors parallel to $\bar{\boldsymbol{k}}_n$,

$$\boldsymbol{k}'_n = \underline{k}_n \frac{\bar{\boldsymbol{k}}_n}{\underline{k}_n}, \quad \boldsymbol{k}'_{n+1} = \underline{k}_{n+1} \frac{\bar{\boldsymbol{k}}_n}{\underline{k}_n},$$

and then rotating these vectors by an amount of $\cos\psi_n = \frac{\boldsymbol{k}_n \cdot \boldsymbol{k}}{\underline{k}_n \underline{k}}$. The emitted particle cannot have more momentum than the emitter has in the Born phase space. Thus, there is an upper bound for ξ, determined by the condition $k_{n+1}^0 = \bar{\underline{k}}_n$, which is equal to

$$\xi_{\max} = \frac{2}{\bar{\underline{k}}_n} q^0.$$

      xi_max = two * uk_n_born / q0
    end function get_xi_max_fsr_massless
```

The computation of $\xi_{\max}$ for massive emitters is described in arXiv:1202.0465. Let's recapitulate it here.

We consider the Dalitz-domain created by k_{n+1}^0, k_n^0 and k_{rec}^0 and introduce the parameterization

$$k_n^0 = \bar{k}_n^0 - z k_{n+1}^0$$

Then, for each value of z, there exists a maximum value of $\underline{k}_{n+1}$ from which $\xi_{\max}$ can be extracted via $\xi_{\max} = 2 k_{n+1}^0/q$. It is determined by the condition

$$\underline{k}_{n+1} \pm \underline{k}_n \pm \underline{k}_{\mathrm{rec}} = 0.$$

This can be manipulated to yield

$$\left(\underline{k}_{n+1}^2 + \underline{k}_n^2 - \underline{k}_{\mathrm{rec}}^2 \right)^2 = 4 \underline{k}_{n+1}^2 \underline{k}_n^2.$$

Here we can use $\underline{k}_n^2 = \left(k_n^0 \right)^2 - m^2$ and $\underline{k}_{\mathrm{rec}}^2 = \left(q - k_n^0 - k_{n+1}^0 \right)^2 - M_{\mathrm{rec}}^2$, as well as the above parameterization of k_n^0, to obtain

$$4 \underline{k}_{n+1}^2 \left(2 \underline{k}_{n+1} q z (1 - z) + q^2 z^2 - 2 q \bar{k}_{\mathrm{rec}}^0 z + M_{\mathrm{rec}}^2 \right) = 0.$$

Solving for k_{n+1}^0 gives

$$k_{n+1}^0 = \frac{2 q \bar{k}_{\mathrm{rec}}^0 z - q^2 z^2 - M_{\mathrm{rec}}^2}{2 q z (1 - z)}. \tag{19.67}$$

It is still open how to compute z. For this, consider that the right-hand-side of equation (19.67) vanishes for

$$z_{1,2} = \left(\bar{k}_{\mathrm{rec}}^0 \pm \sqrt{\left(\bar{k}_{\mathrm{rec}}^0 \right)^2 - M_{\mathrm{rec}}^2} \right) / q,$$

which corresponds to the borders of the Dalitz-region where the gluon momentum vanishes. Thus we define

$$z = z_2 - \frac{1}{2} (z_2 - z_1)(1 + y).$$

The real phase space for an inital-state emission involved in a decay process is generated by first setting the gluon momentum like in the scattering case by using its angular coordinates y and ϕ and then adjusting the gluon energy with ξ. The emitter momentum is kept identical to the Born case, i.e. $p_{\text{in}} = \bar{p}_{\text{in}}$, so that after the emission it has momentum $p_{\text{virt}} = p_{\text{in}} - p_{\text{g}}$ and invariant mass $m^2 = p_{\text{virt}}^2$. Note that the final state momenta have to remain on-shell, so that $p_1^2 = \bar{p}_1^2 = m_1^2$ and $p_2^2 = \bar{p}_2^2 = m_2^2$. Let Λ be the boost from into the rest frame of the emitter after emission, i.e. $\Lambda p_{\text{virt}} = (m, 0, 0, 0)$. In this reference frame, the spatial components of the final-state momenta sum up to zero, and their magnitude is

$$p = \frac{\sqrt{\lambda(m^2, m_1^2, m_2^2)}}{2m},$$

a fact already used in the evaluation of the phase space trees of `phs_forest`. Obviously, from this, the final-state energies can be deferred via $E_i^2 = m_i^2 - p^2$. In the next step, the $p_{1,2}$ are set up as vectors $(E, 0, 0, \pm p)$ along the z-axis and then rotated about the same azimuthal and polar angles as in the Born system. Finally, the momenta are boosted out of the rest frame by multiplying with Λ.

Configure channel mappings, using some conditions from the phase space configuration. If there are no structure functions, we enable a default setup with a single (dummy) structure-function channel. Otherwise, we look at the channel collection that we got from the phase-space configuration step. Each entry should be translated into an independent structure-function channel, where typically there is one default entry, which could be mapped using a standard s-channel mapping if the structure function setup recommends this, and other entries with s-channel resonances. The latter need to be translated into global mappings from the structure-function chain.

@

19.13   A lexer for O'Mega's phase-space output

This module provides three data types. One of them is the type dag_string_t
which should contain the information of all Feynman diagrams in the factorized
form which is provided by O'Mega in its phase-space outout. This output
is translated into a string of tokens (in the form of an a array of the type
dag_token_t) which have a certain meaning. The purpose of this module is
only to identify these tokens correctly and to provide some procedures and
interfaces which allow us to use these strings in a similar way as variables of
the basic character type or the type iso_varying_string. Both character
and iso_varying_string have some disadvantages at least if one wants to keep
support for some older compiler versions. These can be circumvented by the
dag_string_t type. Finally the dag_chain_t type is used to create a larger
string in several steps without always recreating the string, which is done in the
form of a simple linked list. In the end one can create a single dag_string out
of this list, which is more useful.

⟨cascades2_lexer.f90⟩≡
  ⟨File header⟩

  module cascades2_lexer

```

⟨*Cascades2 lexer: procedures*⟩

```
end module cascades2_lexer
```

This is the token type. By default the variable `type` is `EMPTY_TK` but can obtain other values corresponding to the parameters defined below. The type of the token corresponds to a particular sequence of characters. When the token corresponds to a node of a tree, i.e. some particle in the Feynman diagram, the type is `NODE_TK` and the `particle_name` variable is holding the name of the particle. O'Megas output contains in addition to the particle name some numbers which indicate the external momenta that are flowing through this line. These numbers are translated into a binary code and saved in the variable `bincode`. In this case the number 1 corresponds to a bit set at position 0, 2 corresponds to a bit set at position 1, etc. Instead of numbers which are composed out of several digits, letters are used, i.e. A instead of 10 (bit at position 9), B instead of 11 (bit at position 10), etc.

When the DAG is reconstructed from a `dag_string` which was built from O'Mega's output, this string is modified such that a substring (a set of tokens) is replaced by a single token where the type variable is one of the three parameters `DAG_NODE_TK`, `DAG_OPTIONS_TK` and `DAG_COMBINATION_TK`. These parameters correspond to the three types `dag_node_t`, `dag_options_t` and `dag_combination_t` (see `cascades2` for more information. In this case, since these objects are organized in arrays, the `index` variable holds the corresponding position in the array.

In any case, we want to be able to reproduce the character string from which a token (or a string) has been created. The variable `char_len` is the length of this string. For tokens with the type `DAG_NODE_TK`, `DAG_OPTIONS_TK` and `DAG_COMBINATION_TK` we use output of the form `<N23>`, `<O23>` or `<C23>` which is useful for debugging the parser. Here 23 is the `index` and N, O or C obviously corresponds to the `type`.

⟨*Cascades2 lexer: parameters*⟩≡
```
    integer, parameter :: PRT_NAME_LEN = 20
```

⟨*Cascades2 lexer: public*⟩≡
```
    public :: dag_token_t
```

⟨*Cascades2 lexer: types*⟩≡
```
    type :: dag_token_t
       integer :: type = EMPTY_TK
       integer :: char_len = 0
       integer(TC) :: bincode = 0
       character (PRT_NAME_LEN) :: particle_name=""
       integer :: index = 0
     contains
       ⟨Cascades2 lexer: dag token: TBP⟩
    end type dag_token_t
```

This is the string type. It also holds the number of characters in the corre-

sponding character string. It contains an array of tokens. If the dag_string is constructed using the type dag_chain_t, which creates a linked list, we also need the pointer next.

⟨*Cascades2 lexer: public*⟩+≡
```
public :: dag_string_t
```

⟨*Cascades2 lexer: types*⟩+≡
```
type :: dag_string_t
   integer :: char_len = 0
   type (dag_token_t), dimension(:), allocatable :: t
   type (dag_string_t), pointer :: next => null ()
 contains
   ⟨Cascades2 lexer: dag string: TBP⟩
end type dag_string_t
```

This is the chain of dag_strings. It allows us to construct a large string by appending new strings to the linked list, which can later be merged to a single string. This is very useful because the file written by O'Mega contains large strings where each string contains all Feynman diagrams in a factorized form, but these large strings are cut into several pieces and distributed over many lines. As the file can become large, rewriting a new dag_string (or iso_varying_string) would consume more and more time with each additional line. For recreating a single dag_string out of this chain, we need the total character length and the sum of all sizes of the dag_token arrays t.

⟨*Cascades2 lexer: public*⟩+≡
```
public :: dag_chain_t
```

⟨*Cascades2 lexer: types*⟩+≡
```
type :: dag_chain_t
   integer :: char_len = 0
   integer :: t_size = 0
   type (dag_string_t), pointer :: first => null ()
   type (dag_string_t), pointer :: last => null ()
 contains
   ⟨Cascades2 lexer: dag chain: TBP⟩
end type dag_chain_t
```

We define two parameters holding the characters corresponding to a backslash and a blanc space.

⟨*Cascades2 lexer: parameters*⟩+≡
```
character(len=1), parameter, public :: BACKSLASH_CHAR = "\\"
character(len=1), parameter :: BLANC_CHAR = " "
```

These are the parameters which correspond to meaningful types of token.

⟨*Cascades2 lexer: parameters*⟩+≡
```
integer, parameter, public :: NEW_LINE_TK = -2
integer, parameter :: BLANC_SPACE_TK = -1
integer, parameter :: EMPTY_TK = 0
integer, parameter, public :: NODE_TK = 1
integer, parameter, public :: DAG_NODE_TK = 2
integer, parameter, public :: DAG_OPTIONS_TK = 3
integer, parameter, public :: DAG_COMBINATION_TK = 4
integer, parameter, public :: COLON_TK = 11
```

```
integer, parameter, public :: COMMA_TK = 12
integer, parameter, public :: VERTICAL_BAR_TK = 13
integer, parameter, public :: OPEN_PAR_TK = 21
integer, parameter, public :: CLOSED_PAR_TK = 22
integer, parameter, public :: OPEN_CURLY_TK = 31
integer, parameter, public :: CLOSED_CURLY_TK = 32
```

Different sorts of assignment. This contains the conversion of a `character` variable into a `dag_token` or `dag_string`.

⟨*Cascades2 lexer: public*⟩+≡
```
public :: assignment (=)
```

⟨*Cascades2 lexer: interfaces*⟩≡

Compare strings/tokens/characters. Each character is relevant, including all
blanc spaces. An exception is the `newline` character which is not treated by the
types used in this module (not to confused with the type parameter NEW_LINE_TK
which corresponds to the backslash character and simply tells us that the string
continues on the next line in the file).

      allocate (dag_string%t(n_keep))
      dag_string%t = tmp_token(:n_keep)
    end subroutine dag_string_clean
```

If we operate explicitly on the `token` array `t` of a `dag_string`, the variable `char_len` is not automatically modified. It can however be determined afterwards using the following subroutine.

⟨*Cascades2 lexer: dag string: TBP*⟩+≡
```
    procedure :: update_char_len => dag_string_update_char_len
```

⟨*Cascades2 lexer: procedures*⟩+≡
```
    subroutine dag_string_update_char_len (dag_string)
      class (dag_string_t), intent (inout) :: dag_string
      integer :: char_len
      integer :: i
      char_len = 0
      if (allocated (dag_string%t)) then
         do i=1, size (dag_string%t)
            char_len = char_len + dag_string%t(i)%char_len
         enddo
      end if
      dag_string%char_len = char_len
    end subroutine dag_string_update_char_len
```

Append a `dag_string` to a `dag_chain`. The argument `char_string` is of type `character` because the subroutine is used for reading from the file produced by O'Mega which is first read line by line to a character variable.

⟨*Cascades2 lexer: dag chain: TBP*⟩≡
```
    procedure :: append => dag_chain_append_string
```

⟨*Cascades2 lexer: procedures*⟩+≡
```
    subroutine dag_chain_append_string (dag_chain, char_string)
      class (dag_chain_t), intent (inout) :: dag_chain
      character (len=*), intent (in) :: char_string
      if (.not. associated (dag_chain%first)) then
         allocate (dag_chain%first)
         dag_chain%last => dag_chain%first
      else
         allocate (dag_chain%last%next)
         dag_chain%last => dag_chain%last%next
      end if
      dag_chain%last = char_string
      dag_chain%char_len = dag_chain%char_len + dag_chain%last%char_len
      dag_chain%t_size = dag_chain%t_size + size (dag_chain%last%t)
    end subroutine dag_chain_append_string
```

Reduce the linked list of `dag_string` objects which are attached to a given `dag_chain` object to a single `dag_string`.

⟨*Cascades2 lexer: dag chain: TBP*⟩+≡
```
    procedure :: compress => dag_chain_compress
```

⟨*Cascades2 lexer: procedures*⟩+≡
```
    subroutine dag_chain_compress (dag_chain)
      class (dag_chain_t), intent (inout) :: dag_chain
      type (dag_string_t), pointer :: current
      type (dag_string_t), pointer :: remove
      integer :: filled_t
      current => dag_chain%first
      dag_chain%first => null ()
      allocate (dag_chain%first)
      dag_chain%last => dag_chain%first
      dag_chain%first%char_len = dag_chain%char_len
      allocate (dag_chain%first%t (dag_chain%t_size))
      filled_t = 0
      do while (associated (current))
        dag_chain%first%t(filled_t+1:filled_t+size(current%t)) = current%t
        filled_t = filled_t + size (current%t)
        remove => current
        current => current%next
        deallocate (remove)
      enddo
    end subroutine dag_chain_compress
```

Finalizer for `dag_string_t`.

⟨*Cascades2 lexer: dag string: TBP*⟩+≡
```
    procedure :: final => dag_string_final
```

⟨*Cascades2 lexer: procedures*⟩+≡

19.14   An alternative cascades module

This module might replace the module `cascades`, which generates suitable phase space parametrizations and generates the phase space file. The mappings, as well as the criteria to determine these, do not change.

The advantage of this module is that it makes use of the O'Mega matrix element generator which provides the relevant Feynman diagrams (the ones which can be constructed only from 3-vertices). In principle, the construction of these diagrams is also one of the tasks of the existing `cascades` module, in which the diagrams would correspond to a set of cascades. It starts by creating cascades which correspond to the outgoing particles. These are combined to a new cascade using the vertices of the model. In this way, since each cascade knows the daughter cascades from which it is built, complete Feynman diagrams

are represented by sets of cascades, as soon as the existing cascades can be recombined with the incoming particle(s).

In this module, the Feynman diagrams are represented by the type `feyngraph_t`, which represents the Feynman diagrams as a tree of nodes. The object which contains the necessary kinematical information to determine mappings, and hence sensible phase space parametrizations is of another type, called `kingraph_t`, which is built from a corresponding `feyngraph` object.

There are two types of output which can be produced by `O'Mega` and are potentially relevant here. The first type contains all tree diagrams for the process under consideration, where each line of the output corresponds to one Feynman diagram. This output is easy to read, but can be very large, depending on the number of particles involved in the process. Moreover, it repeats substructures of the diagrams which are part of more than one diagram. One could in principle work with this output and construct a `feyngraph` from each line, if allowed, i.e. if there are only 3-vertices.

The other output contains also all of these Feynman diagrams, but in a factorized form. This means that the substructures which appear in several Feynman diagrams, are written only once, if possible. This leads to a much shorter input file, which speeds up the parsing process. Furthermore it makes it possible to reconstruct the `feyngraphs` in such a way that the calculations concerning subdiagrams which reappear in other `feyngraphs` have to be performed only once. This is already the case in the existing `cascades` module but can be exploited more efficiently here because the possible graphs are well known from the input file, whereas the `cascades` module would create a large number of `cascades` which do not lead to a complete Feynman diagram of the given process.

19.14.1 Particle properties

We define a type holding the properties of the particles which are needed for parsing and finding the phase space parametrizations and mappings. The properties of all particles which appear in the parsed Feynman diagrams for the given process will be stored in a central place, and only pointers to these objects are used.

⟨*Cascades2: types*⟩≡
```
    type :: part_prop_t
      character (len=LABEL_LEN) :: particle_label
      integer :: pdg = 0
      real(default) :: mass = 0.
      real :: width = 0.
      integer :: spin_type = 0
      logical :: is_vector = .false.
      logical :: empty = .true.
      type (part_prop_t), pointer :: anti => null ()
      type (string_t) :: tex_name
     contains
     ⟨Cascades2: part prop: TBP⟩
    end type part_prop_t
```

The `particle_label` in `part_prop_t` is simply the particle name (e.g. 'W+'). The corresponding variable in the type `f_node_t` contains some additional information related to the external momenta, see below. The length of the `character` variable is fixed as:

⟨*Cascades2: parameters*⟩≡
```
    integer, parameter :: LABEL_LEN=30
```

⟨*Cascades2: part prop: TBP*⟩≡
```
  procedure :: final => part_prop_final
```

⟨*Cascades2: procedures*⟩≡
```
    subroutine part_prop_final (part)
      class(part_prop_t), intent(inout) :: part
      part%anti => null ()
    end subroutine part_prop_final
```

19.14.2 The mapping modes

The possible mappings are essentially the same as in `cascades`, but we introduce in addition the mapping constant NON_RESONANT, which does not refer to a new mapping; it corresponds to the nonresonant version of a potentially resonant particle (or k_node). This becomes relevant when we compare k_nodes to eliminate equivalences.

⟨*Cascades2: parameters*⟩+≡

```
integer, parameter :: &
     & NONRESONANT = -2, EXTERNAL_PRT = -1, &
     & NO_MAPPING = 0, S_CHANNEL = 1, T_CHANNEL =  2, U_CHANNEL = 3, &
     & RADIATION = 4, COLLINEAR = 5, INFRARED = 6, &
     & STEP_MAPPING_E = 11, STEP_MAPPING_H = 12, &
     & ON_SHELL = 99
```

19.14.3 Grove properties

The channels or `kingraphs` will be grouped in groves, i.e. sets of channels, which share some characteristic numbers. These numbers are stored in the following type:

⟨*Cascades2: types*⟩+≡

```
type :: grove_prop_t
   integer :: multiplicity = 0
   integer :: n_resonances = 0
   integer :: n_log_enhanced = 0
   integer :: n_off_shell = 0
   integer :: n_t_channel = 0
   integer :: res_hash = 0
end type grove_prop_t
```

19.14.4 The tree type

This type contains all the information which is needed to reconstruct a `feyngraph` or `kingraph`. We store bincodes, pdg codes and mappings for all nodes of a valid `kingraph`. If we label the external particles as given in the process definition with integer numbers representing their position in the process definition, the bincode would be the number that one obtains by setting the bit at the position that is given by this number. If we combine two particles/nodes to a third one (using a three-vertex of the given model), the bincode is the number which one obtains by setting all the bits which are set for the two particles. The `pdg` and `mapping` are simply the pdg-code and mapping at the position (i.e. propagator or external particle) which is specified by the corresponding bincode. We use `tree_t` not only for completed `kingraphs`, but also for all k_nodes, which are a subtree of a `kingraph`.

⟨*Cascades2: types*⟩+≡

```
type :: tree_t
   integer(TC), dimension(:), allocatable :: bc
   integer, dimension(:), allocatable :: pdg
   integer, dimension(:), allocatable :: mapping
   integer :: n_entries = 0
```

```
      logical :: keep = .true.
      logical :: empty = .true.
   contains
   ⟨Cascades2: tree: TBP⟩
   end type tree_t
```

⟨*Cascades2: tree: TBP*⟩≡
```
   procedure :: final => tree_final
```

⟨*Cascades2: procedures*⟩+≡
```
   subroutine tree_final (tree)
     class (tree_t), intent (inout) :: tree
     if (allocated (tree%bc)) deallocate (tree%bc)
     if (allocated (tree%pdg)) deallocate (tree%pdg)
     if (allocated (tree%mapping)) deallocate (tree%mapping)
   end subroutine tree_final
```

⟨*Cascades2: interfaces*⟩≡
```
   interface assignment (=)
      module procedure tree_assign
   end interface assignment (=)
```

⟨*Cascades2: procedures*⟩+≡
```
   subroutine tree_assign (tree1, tree2)
     type (tree_t), intent (inout) :: tree1
     type (tree_t), intent (in) :: tree2
     if (allocated (tree2%bc)) then
        allocate (tree1%bc(size(tree2%bc)))
        tree1%bc = tree2%bc
     end if
     if (allocated (tree2%pdg)) then
        allocate (tree1%pdg(size(tree2%pdg)))
        tree1%pdg = tree2%pdg
     end if
     if (allocated (tree2%mapping)) then
        allocate (tree1%mapping(size(tree2%mapping)))
        tree1%mapping = tree2%mapping
     end if
     tree1%n_entries = tree2%n_entries
     tree1%keep = tree2%keep
     tree1%empty = tree2%empty
   end subroutine tree_assign
```

19.14.5   Add entries to the tree

The following procedures fill the arrays in `tree_t` with entries resulting from
the bincode and mapping assignment.

⟨*Cascades2: tree: TBP*⟩+≡
```
   procedure :: add_entry_from_numbers => tree_add_entry_from_numbers
   procedure :: add_entry_from_node => tree_add_entry_from_node
   generic :: add_entry =>  add_entry_from_numbers, add_entry_from_node
```

Here we add a single entry to each of the arrays. This will exclusively be used
for external particles.

⟨*Cascades2: procedures*⟩+≡

```
subroutine tree_add_entry_from_numbers (tree, bincode, pdg, mapping)
  class (tree_t), intent (inout) :: tree
  integer(TC), intent (in) :: bincode
  integer, intent (in) :: pdg
  integer, intent (in) :: mapping
  integer :: pos
  if (tree%empty) then
     allocate (tree%bc(1))
     allocate (tree%pdg(1))
     allocate (tree%mapping(1))
     pos = tree%n_entries + 1
     tree%bc(pos) = bincode
     tree%pdg(pos) = pdg
     tree%mapping(pos) = mapping
     tree%n_entries = pos
     tree%empty = .false.
  end if
end subroutine tree_add_entry_from_numbers
```

Here we merge two existing subtrees and a single entry (bc, pdg and mapping).

⟨*Cascades2: procedures*⟩+≡

```
subroutine tree_merge (tree, tree1, tree2, bc, pdg, mapping)
  class (tree_t), intent (inout) :: tree
  type (tree_t), intent (in) :: tree1, tree2
  integer(TC), intent (in) :: bc
  integer, intent (in) :: pdg, mapping
  integer :: tree_size
  integer :: i1, i2
  if (tree%empty) then
     i1 = tree1%n_entries
     i2 = tree1%n_entries + tree2%n_entries
     tree_size = tree1%n_entries + tree2%n_entries + 1
     allocate (tree%bc (tree_size))
     allocate (tree%pdg (tree_size))
     allocate (tree%mapping (tree_size))
     tree%bc(:i1) = tree1%bc
     tree%pdg(:i1) = tree1%pdg
     tree%mapping(:i1) = tree1%mapping
     tree%bc(i1+1:i2) = tree2%bc
     tree%pdg(i1+1:i2) = tree2%pdg
     tree%mapping(i1+1:i2) = tree2%mapping
     tree%bc(tree_size) = bc
     tree%pdg(tree_size) = pdg
     tree%mapping(tree_size) = mapping
     tree%n_entries = tree_size
     tree%empty = .false.
  end if
end subroutine tree_merge
```

Here we add entries to a tree for a given k_node, which means that we first have

to determine whether the node is external or internal. The arrays are sorted after the entries have been added (see below for details).

⟨*Cascades2: procedures*⟩+≡
```
subroutine tree_add_entry_from_node (tree, node)
  class (tree_t), intent (inout) :: tree
  type (k_node_t), intent (in) :: node
  integer :: pdg
  if (node%t_line) then
     pdg = abs (node%particle%pdg)
  else
     pdg = node%particle%pdg
  end if
  if (associated (node%daughter1) .and. &
       associated (node%daughter2)) then
     call tree_merge (tree, node%daughter1%subtree, &
          node%daughter2%subtree, node%bincode, &
          node%particle%pdg, node%mapping)
  else
     call tree_add_entry_from_numbers (tree, node%bincode, &
          node%particle%pdg, node%mapping)
  end if
  call tree%sort ()
end subroutine tree_add_entry_from_node
```

For a well-defined order of the elements of the arrays in `tree_t`, the elements can be sorted. The bincodes (entries of `bc`) are simply ordered by size, the `pdg` and `mapping` entries go to the positions of the corresponding `bc` values.

⟨*Cascades2: tree: TBP*⟩+≡
```
procedure :: sort => tree_sort
```

⟨*Cascades2: procedures*⟩+≡
```
subroutine tree_sort (tree)
  class (tree_t), intent (inout) :: tree
  integer(TC), dimension(size(tree%bc)) :: bc_tmp
  integer, dimension(size(tree%pdg)) :: pdg_tmp, mapping_tmp
  integer, dimension(1) :: pos
  integer :: i
  bc_tmp = tree%bc
  pdg_tmp = tree%pdg
  mapping_tmp = tree%mapping
  do i = size(tree%bc),1,-1
     pos = maxloc (bc_tmp)
     tree%bc(i) = bc_tmp (pos(1))
     tree%pdg(i) = pdg_tmp (pos(1))
     tree%mapping(i) = mapping_tmp (pos(1))
     bc_tmp(pos(1)) = 0
  end do
end subroutine tree_sort
```

19.14.6 Graph types

We define an abstract type which will give rise to two different types: The type `feyngraph_t` contains the pure information of the corresponding Feynman diagram, but also a list of objects of the `kingraph` type which contain the kinematically relevant data for the mapping calculation as well as the mappings themselves. Every graph should have an index which is unique. Graphs which are not needed any more can be disabled by setting the `keep` variable to `false`.

⟨*Cascades2: types*⟩+≡
```
type, abstract :: graph_t
   integer :: index = 0
   integer :: n_nodes = 0
   logical :: keep = .true.
end type graph_t
```

This is the type representing the Feynman diagrams which are read from an input file created by O'Mega. It is a tree of nodes, which we call `f_nodes`, so that `feyngraph_t` contains a pointer to the root of this tree, and each node can have two daughter nodes. The case of only one associated daughter should never appear, because in the method of phase space parametrization which is used here, we combine always two particle momenta to a third one. The `feyngraphs` will be arranged in a linked list. This is why we have a pointer to the next graph. The `kingraphs` on the other hand are arranged in linked lists which are attached to the corresponding `feyngraph`. In general, a `feyngraph` can give rise to more than one `kingraph` because we make a copy every time a particle can be resonant, so that in the copy we keep the particle nonresonant.

⟨*Cascades2: types*⟩+≡
```
type, extends (graph_t) :: feyngraph_t
   type (string_t) :: omega_feyngraph_output
   type (f_node_t), pointer :: root => null ()
   type (feyngraph_t), pointer :: next => null()
   type (kingraph_t), pointer :: kin_first => null ()
   type (kingraph_t), pointer :: kin_last => null ()
 contains
 ⟨Cascades2: feyngraph: TBP⟩
end type feyngraph_t
```

A container for a pointer of type `feyngraph_t`. This is used to realize arrays of these pointers.

⟨*Cascades2: types*⟩+≡
```
type :: feyngraph_ptr_t
   type (feyngraph_t), pointer :: graph => null ()
end type feyngraph_ptr_t
```

The length of a string describing a Feynman diagram which is produced by O'Mega is fixed by the parameter

⟨*Cascades2: parameters*⟩+≡
```
integer, parameter :: FEYNGRAPH_LEN=300
```

⟨*Cascades2: feyngraph: TBP*⟩≡
```
procedure :: final => feyngraph_final
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine feyngraph_final (graph)
      class(feyngraph_t), intent(inout) :: graph
      type (kingraph_t), pointer :: current
      graph%root => null ()
      graph%kin_last => null ()
      do while (associated (graph%kin_first))
         current => graph%kin_first
         graph%kin_first => graph%kin_first%next
         call current%final ()
         deallocate (current)
      enddo
    end subroutine feyngraph_final
```

This is the type of graph which is used to find the phase space channels, or in
other words, each kingraph could correspond to a channel, if it is not eliminated
for kinematical reasons or due to an equivalence. For the linked list which is
attached to the corresponding `feyngraph`, we need the `next` pointer, whereas
`grove_next` points to the next `kingraph` within a grove. The information which
is relevant for the specification of a channel is stored in `tree`. We use `grove_prop`
to sort the `kingraph` in a grove in which all `kingraphs` are characterized by the
numbers contained in `grove_prop`. Later these groves are further subdevided
using the resonance hash. A `kingraph` which is constructed directly from the
output of O'Mega, is not `inverse`. In this case the first incoming particle is
the root ofthe tree. In a scattering process, we can also construct a `kingraph`
where the root of the tree is the second incoming particle. In this case the value
of `inverse` is `.true.`.

⟨*Cascades2: types*⟩+≡
```
    type, extends (graph_t) :: kingraph_t
      type (k_node_t), pointer :: root => null ()
      type (kingraph_t), pointer :: next => null()
      type (kingraph_t), pointer :: grove_next => null ()
      type (tree_t) :: tree
      type (grove_prop_t) :: grove_prop
      logical :: inverse = .false.
      integer :: prc_component = 0
      contains
    ⟨Cascades2: kingraph: TBP⟩
    end type kingraph_t
```

Another container for a pointer to emulate arrays of pointers:

⟨*Cascades2: types*⟩+≡
```
    type :: kingraph_ptr_t
      type (kingraph_t), pointer :: graph => null ()
    end type kingraph_ptr_t
```

⟨*Cascades2: kingraph: TBP*⟩≡
```
    procedure :: final => kingraph_final
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine kingraph_final (graph)
      class(kingraph_t), intent(inout) :: graph
```

```
      graph%root => null ()
      graph%next => null ()
      graph%grove_next => null ()
      call graph%tree%final ()
   end subroutine kingraph_final
```

19.14.7 The node types

We define an abstract type containing variables which are needed for f_node_t as well as k_node_t. We say that a node is on the t-line if it lies between the two nodes which correspond to the two incoming particles. incoming and tline are used only for scattering processes and remain .false. in decay processes. The variable n_subtree_nodes holds the number of nodes (including the node itself) of the subtree of which the node is the root.

⟨*Cascades2: types*⟩+≡
```
   type, abstract :: node_t
      type (part_prop_t), pointer :: particle => null ()
      logical :: incoming = .false.
      logical :: t_line = .false.
      integer :: index = 0
      logical :: keep = .true.
      integer :: n_subtree_nodes = 1
   end type node_t
```

We use two different list types for the different kinds of nodes. We therefore start with an abstract type:

⟨*Cascades2: types*⟩+≡
```
   type, abstract :: list_t
      integer :: n_entries = 0
   end type list_t
```

Since the contents of the lists are different, we introduce two different entry types. Since the trees of nodes use pointers, the nodes should only be allocated by a type-bound procedure of the corresponding list type, such that we can keep track of all nodes, eventually reuse and in the end deallocate nodes correctly, without forgetting any nodes. Here is the type for the k_nodes. The list is a linked list. We want to reuse (recycle) the k_nodes which are neither incoming nore t_line.

⟨*Cascades2: types*⟩+≡
```
   type :: k_node_entry_t
      type (k_node_t), pointer :: node => null ()
      type (k_node_entry_t), pointer :: next => null ()
      logical :: recycle = .false.
    contains
    ⟨Cascades2: k node entry: TBP⟩
   end type k_node_entry_t
```

⟨*Cascades2: k node entry: TBP*⟩≡
```
   procedure :: final => k_node_entry_final
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine k_node_entry_final (entry)
      class(k_node_entry_t), intent(inout) :: entry
      if (associated (entry%node)) then
         call entry%node%final
         deallocate (entry%node)
      end if
      entry%next => null ()
    end subroutine k_node_entry_final
```

⟨*Cascades2: k node entry: TBP*⟩+≡
```
    procedure :: write => k_node_entry_write
```
⟨*Cascades2: procedures*⟩+≡
```
    subroutine k_node_entry_write (k_node_entry, u)
      class (k_node_entry_t), intent (in) :: k_node_entry
      integer, intent (in) :: u
    end subroutine k_node_entry_write
```

Here is the list type for **k_nodes**. A **k_node_list** can be declared to be an observer. In this case it does not create any nodes by itself, but the entries set their pointers to existing nodes. In this way we can use the list structure and the type bound procedures for existing nodes.

⟨*Cascades2: types*⟩+≡
```
    type, extends (list_t) :: k_node_list_t
       type (k_node_entry_t), pointer :: first => null ()
       type (k_node_entry_t), pointer :: last => null ()
       integer :: n_recycle
       logical :: observer = .false.
     contains
     ⟨Cascades2: k node list: TBP⟩
    end type k_node_list_t
```

⟨*Cascades2: k node list: TBP*⟩≡
```
    procedure :: final => k_node_list_final
```
⟨*Cascades2: procedures*⟩+≡
```
    subroutine k_node_list_final (list)
      class(k_node_list_t), intent(inout) :: list
      type (k_node_entry_t), pointer :: current
      do while (associated (list%first))
         current => list%first
         list%first => list%first%next
         if (list%observer) current%node => null ()
         call current%final ()
         deallocate (current)
      enddo
    end subroutine k_node_list_final
```

The **f_node_t** type contains the **particle_label** variable which is extracted from the input file. It consists not only of the particle name, but also of some numbers in brackets. These numbers indicate which external particles are part of the subtree of this node. The **f_node** contains also a list of **k_nodes**. Therefore,

if the nodes are not `incoming` or `t_line`, the mapping calculations for these `k_nodes` which can appear in several `kingraphs` have to be performed only once.

⟨*Cascades2: types*⟩+≡
```
type, extends (node_t) :: f_node_t
  type (f_node_t), pointer :: daughter1 => null ()
  type (f_node_t), pointer :: daughter2 => null ()
  character (len=LABEL_LEN) :: particle_label
  type (k_node_list_t) :: k_node_list
 contains
 ⟨Cascades2: f node: TBP⟩
 end type f_node_t
```

The finalizer nullifies the daughter pointers, since they are deallocated, like the `f_node` itself, with the finalizer of the `f_node_list`.

⟨*Cascades2: f node: TBP*⟩≡
```
procedure :: final => f_node_final
```

⟨*Cascades2: procedures*⟩+≡
```
recursive subroutine f_node_final (node)
  class(f_node_t), intent(inout) :: node
  call node%k_node_list%final ()
  node%daughter1 => null ()
  node%daughter2 => null ()
end subroutine f_node_final
```

Finaliser for `f_node_entry`.

⟨*Cascades2: f node entry: TBP*⟩≡
```
procedure :: final => f_node_entry_final
```

⟨*Cascades2: procedures*⟩+≡
```
subroutine f_node_entry_final (entry)
  class(f_node_entry_t), intent(inout) :: entry
  if (associated (entry%node)) then
     call entry%node%final ()
     deallocate (entry%node)
  end if
  entry%next => null ()
end subroutine f_node_entry_final
```

Set index if not yet done, i.e. if it is zero.

⟨*Cascades2: f node: TBP*⟩+≡
```
procedure :: set_index => f_node_set_index
```

⟨*Cascades2: procedures*⟩+≡
```
subroutine f_node_set_index (f_node)
  class (f_node_t), intent (inout) :: f_node
  integer, save :: counter = 0
  if (f_node%index == 0) then
     counter = counter + 1
     f_node%index = counter
  end if
end subroutine f_node_set_index
```

Type for the nodes of the tree (lines of the Feynman diagrams). We also need a type containing a pointer to a node, which is needed for creating arrays of pointers. This will be used for scattering processes where we can take either the first or the second particle to be the root of the tree. Since we need both cases for the calculations and O'Mega only gives us one of these, we have to perform a transformation of the graph in which some nodes (on the line which we hereafter call t-line) need to know their mother and sister nodes, which become their daughters within this transformation.

⟨*Cascades2: types*⟩+≡
```
    type :: f_node_ptr_t

  if (k_node%index == 0) then
     counter = counter + 1
     k_node%index = counter
  end if
end subroutine k_node_set_index
```

The process type (decay or scattering) is given by an integer which is equal to the number of incoming particles.

⟨*Cascades2: public*⟩≡
```
public :: DECAY, SCATTERING
```

⟨*Cascades2: parameters*⟩+≡
```
integer, parameter :: DECAY=1, SCATTERING=2
```

The entries of the **f node list** contain the substring of the input file from which the node's subtree will be constructed (or a modified string containing placeholders for substrings). We use the length of this string for fast comparison to find the nodes in the **f node list** which we want to reuse.

⟨*Cascades2: types*⟩+≡
```
type :: f_node_entry_t
   character (len=FEYNGRAPH_LEN) :: subtree_string
   integer :: string_len = 0
   type (f_node_t), pointer :: node => null ()
   type (f_node_entry_t), pointer :: next => null ()
   integer :: subtree_size = 0
 contains
   ⟨Cascades2: f node entry: TBP⟩
end type f_node_entry_t
```

A write method for **f node entry**.

⟨*Cascades2: f node entry: TBP*⟩+≡
```
procedure :: write => f_node_entry_write
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine f_node_entry_write (f_node_entry, u)
      class (f_node_entry_t), intent (in) :: f_node_entry
      integer, intent (in) :: u
      write (unit=u, fmt='(A)') trim(f_node_entry%subtree_string)
    end subroutine f_node_entry_write
```

⟨*Cascades2: interfaces*⟩+≡
```
    interface assignment (=)
       module procedure f_node_entry_assign
    end interface assignment (=)
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine f_node_entry_assign (entry1, entry2)
      type (f_node_entry_t), intent (out) :: entry1
      type (f_node_entry_t), intent (in) :: entry2
      entry1%node => entry2%node
      entry1%subtree_string = entry2%subtree_string
      entry1%string_len = entry2%string_len
      entry1%subtree_size = entry2%subtree_size
    end subroutine f_node_entry_assign
```

This is the list type for **f_nodes**. The variable **max_tree_size** is the number of
nodes which appear in a complete graph.

⟨*Cascades2: types*⟩+≡
```
    type, extends (list_t) :: f_node_list_t
       type (f_node_entry_t), pointer :: first => null ()
       type (f_node_entry_t), pointer :: last => null ()
       type (k_node_list_t), pointer :: k_node_list => null ()
       integer :: max_tree_size = 0
     contains
     ⟨Cascades2: f node list: TBP⟩
    end type f_node_list_t
```

Add an entry to the **f_node_list**. If the node might be reused, we check first
using the **subtree_string** if there is already a node in the list which is the root
of exactly the same subtree. Otherwise we add an entry to the list and allocate
the node. In both cases we return a pointer to the node which allows to access
the node.

⟨*Cascades2: f node list: TBP*⟩≡
```
    procedure :: add_entry => f_node_list_add_entry
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine f_node_list_add_entry (list, subtree_string, ptr_to_node, &
        recycle, subtree_size)
      class (f_node_list_t), intent (inout) :: list
      character (len=*), intent (in) :: subtree_string
      type (f_node_t), pointer, intent (out) :: ptr_to_node
      logical, intent (in) :: recycle
      integer, intent (in), optional :: subtree_size
      type (f_node_entry_t), pointer :: current
      type (f_node_entry_t), pointer :: second
      integer :: subtree_len
```

```
        ptr_to_node => null ()
        if (recycle) then
            subtree_len = len_trim (subtree_string)
            current => list%first
            do while (associated (current))
                if (present (subtree_size)) then
                    if (current%subtree_size /= subtree_size) exit
                end if
                if (current%string_len == subtree_len) then
                    if (trim (current%subtree_string) == trim (subtree_string)) then
                        ptr_to_node => current%node
                        exit
                    end if
                end if
                current => current%next
            enddo
        end if
        if (.not. associated (ptr_to_node)) then
            if (list%n_entries == 0) then
                allocate (list%first)
                list%last => list%first
            else
                second => list%first
                list%first => null ()
                allocate (list%first)
                list%first%next => second
            end if
            list%n_entries = list%n_entries + 1
            list%first%subtree_string = trim(subtree_string)
            list%first%string_len = subtree_len
            if (present (subtree_size)) list%first%subtree_size = subtree_size
            allocate (list%first%node)
            call list%first%node%set_index ()
            ptr_to_node => list%first%node
        end if
    end subroutine f_node_list_add_entry
```

A write method for debugging.

⟨Cascades2: f node list: TBP⟩+≡
```
    procedure :: write => f_node_list_write
```

⟨Cascades2: procedures⟩+≡
```
    subroutine f_node_list_write (f_node_list, u)
      class (f_node_list_t), intent (in) :: f_node_list
      integer, intent (in) :: u
      type (f_node_entry_t), pointer :: current
      integer :: pos = 0
      current => f_node_list%first
      do while (associated (current))
          pos = pos + 1
          write (unit=u, fmt='(A,I10)') 'entry #: ', pos
          call current%write (u)
          write (unit=u, fmt=*)
          current => current%next
```

```
        enddo
    end subroutine f_node_list_write
```

⟨*Cascades2: interfaces*⟩+≡
```
    interface assignment (=)
        module procedure k_node_entry_assign
    end interface assignment (=)
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine k_node_entry_assign (entry1, entry2)
      type (k_node_entry_t), intent (out) :: entry1
      type (k_node_entry_t), intent (in) :: entry2
      entry1%node => entry2%node
      entry1%recycle = entry2%recycle
    end subroutine k_node_entry_assign
```

Add an entry to the k node list. We have to specify if the node can be reused.
The check for existing reusable nodes happens with k node list get nodes (see
below).

⟨*Cascades2: k node list: TBP*⟩+≡
```
    procedure :: add_entry => k_node_list_add_entry
```

⟨*Cascades2: procedures*⟩+≡
```
    recursive subroutine k_node_list_add_entry (list, ptr_to_node, recycle)
      class (k_node_list_t), intent (inout) :: list
      type (k_node_t), pointer, intent (out) :: ptr_to_node
      logical, intent (in) :: recycle
      if (list%n_entries == 0) then
         allocate (list%first)
         list%last => list%first
      else
         allocate (list%last%next)
         list%last => list%last%next
      end if
      list%n_entries = list%n_entries + 1
      list%last%recycle = recycle
      allocate (list%last%node)
      call list%last%node%set_index ()
      ptr_to_node => list%last%node
    end subroutine k_node_list_add_entry
```

We need a similar subroutine for adding only a pointer to a list. This is needed
for a k node list which is only an observer, i.e. it does not create any nodes
by itself.

⟨*Cascades2: k node list: TBP*⟩+≡
```
    procedure :: add_pointer => k_node_list_add_pointer
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine k_node_list_add_pointer (list, ptr_to_node, recycle)
      class (k_node_list_t), intent (inout) :: list
      type (k_node_t), pointer, intent (in) :: ptr_to_node
      logical, optional, intent (in) :: recycle
      logical :: rec
      if (present (recycle)) then
```

```
      rec = recycle
   else
      rec = .false.
   end if
   if (list%n_entries == 0) then
      allocate (list%first)
      list%last => list%first
   else
      allocate (list%last%next)
      list%last => list%last%next
   end if
   list%n_entries = list%n_entries + 1
   list%last%recycle = rec
   list%last%node => ptr_to_node
end subroutine k_node_list_add_pointer
```

The **k node list** can also be used to collect **k nodes** which belong to different **f nodes** in order to compare these. This is done only for nodes which have the same number of subtree nodes. We compare all nodes of the list with each other (as long as the node is not deactivated, i.e. if the **keep** variable is set to **.true.**) using the subroutine **subtree_select**. If it turns out that two nodes are equivalent, we keep only one of them. The term equivalent in this module refers to trees or subtrees which differ in the pdg codes at positions where the trivial mapping is used (**NO MAPPING** or **NON RESONANT**) so that the mass of the particle does not matter. Depending on the available couplings, two equivalent subtrees could eventually lead to the same phase space channels, which is why only one of them is kept.

⟨*Cascades2: k node list: TBP*⟩+≡
```
   procedure :: check_subtree_equivalences => k_node_list_check_subtree_equivalences
```

⟨*Cascades2: procedures*⟩+≡
```
   subroutine k_node_list_check_subtree_equivalences (list, model)
     class (k_node_list_t), intent (inout) :: list
     type (model_data_t), intent (in) :: model
     type (k_node_ptr_t), dimension (:), allocatable :: set
     type (k_node_entry_t), pointer :: current
     integer :: pos
     integer :: i,j
     if (list%n_entries == 0) return
     allocate (set (list%n_entries))
     current => list%first
     pos = 0
     do while (associated (current))
        pos = pos + 1
        set(pos)%node => current%node
        current => current%next
     enddo
     do i=1, list%n_entries
        if (set(i)%node%keep) then
           do j=i+1, list%n_entries
              if (set(j)%node%keep) then
                 if (set(i)%node%bincode == set(j)%node%bincode) then
                    call subtree_select (set(i)%node%subtree,set(j)%node%subtree, model)
```

```
                    if (.not. set(i)%node%subtree%keep) then
                        set(i)%node%keep = .false.
                        exit
                    else if (.not. set(j)%node%subtree%keep) then
                        set(j)%node%keep = .false.
                    end if
                end if
            end if
        enddo
    end if
enddo
deallocate (set)
end subroutine k_node_list_check_subtree_equivalences
```

This subroutine is used to obtain all **k nodes** of a **k node list** which can be recycled and are not disabled for some reason. We pass an allocatable array of the type **k node ptr t** which will be allocated if there are any such nodes in the list and the pointers will be associated with these nodes.

⟨*Cascades2: k node list: TBP*⟩+≡

   end subroutine f_node_list_final
```

19.14.8 The grove list

First a type is introduced in order to speed up the comparison of kingraphs
with the purpose to quickly find the graphs that might be equivalent. This is
done solely on the basis of a number (which is given by the value of `depth` in
`compare_tree_t`) of bincodes, which are the highest ones that do not belong to
external particles. The highest such value determines the index of the element
in the `entry` array of the `compare_tree`. The next lower such value determines
the index of the element in the `entry` array of this `entry`, and so on and so
forth. This results in a tree structure where the number of levels is given by
`depth` and should not be too large for reasons of memory. This is the entry
type.

⟨*Cascades2: types*⟩+≡
```
   type :: compare_tree_entry_t
     type (compare_tree_entry_t), dimension(:), pointer :: entry => null ()
     type (kingraph_ptr_t), dimension(:), allocatable :: graph_entry
    contains
     ⟨Cascades2: compare tree entry: TBP⟩
   end type compare_tree_entry_t
```

This is the tree type.

⟨*Cascades2: types*⟩+≡
```
   type :: compare_tree_t
     integer :: depth = 3
     type (compare_tree_entry_t), dimension(:), pointer :: entry => null ()
```

```
      contains
        ⟨Cascades2: compare tree: TBP⟩
      end type compare_tree_t
```

Finalizers for both types. The one for the entry type has to be recursive.

⟨*Cascades2: compare tree: TBP*⟩≡
```
      procedure :: final => compare_tree_final
```

⟨*Cascades2: procedures*⟩+≡
```
      subroutine compare_tree_final (ctree)
        class (compare_tree_t), intent (inout) :: ctree
        integer :: i
        if (associated (ctree%entry)) then
           do i=1, size (ctree%entry)
              call ctree%entry(i)%final ()
              deallocate (ctree%entry)
           end do
        end if
      end subroutine compare_tree_final
```

⟨*Cascades2: compare tree entry: TBP*⟩≡
```
      procedure :: final => compare_tree_entry_final
```

⟨*Cascades2: procedures*⟩+≡
```
      recursive subroutine compare_tree_entry_final (ct_entry)
        class (compare_tree_entry_t), intent (inout) :: ct_entry
        integer :: i
        if (associated (ct_entry%entry)) then
           do i=1, size (ct_entry%entry)
              call ct_entry%entry(i)%final ()
           enddo
           deallocate (ct_entry%entry)
        else
           deallocate (ct_entry%graph_entry)
        end if
      end subroutine compare_tree_entry_final
```

Check the presence of a graph which is considered as equivalent and select between the two. If there is no such graph, the current one is added to the list. First the entry has to be found:

⟨*Cascades2: compare tree: TBP*⟩+≡
```
      procedure :: check_kingraph => compare_tree_check_kingraph
```

⟨*Cascades2: procedures*⟩+≡
```
      subroutine compare_tree_check_kingraph (ctree, kingraph, model, preliminary)
        class (compare_tree_t), intent (inout) :: ctree
        type (kingraph_t), intent (inout), pointer :: kingraph
        type (model_data_t), intent (in) :: model
        logical, intent (in) :: preliminary
        integer :: i
        integer :: pos
        integer(TC) :: sz
        integer(TC), dimension(:), allocatable :: identifier
        if (.not. associated (ctree%entry)) then
```

```
      sz = 0_TC
      do i = size(kingraph%tree%bc), 1, -1
         sz = ior (sz, kingraph%tree%bc(i))
      enddo
      if (sz > 0) then
         allocate (ctree%entry (sz))
      else
         call msg_bug ("Compare tree could not be created")
      end if
   end if
   allocate (identifier (ctree%depth))
   pos = 0
   do i = size(kingraph%tree%bc), 1, -1
      if (popcnt (kingraph%tree%bc(i)) /= 1) then
         pos = pos + 1
         identifier(pos) = kingraph%tree%bc(i)
         if (pos == ctree%depth) exit
      end if
   enddo
   if (size (identifier) > 1) then
      call ctree%entry(identifier(1))%check_kingraph (kingraph, model, &
           preliminary, identifier(1), identifier(2:))
   else if (size (identifier) == 1) then
      call ctree%entry(identifier(1))%check_kingraph (kingraph, model, preliminary)
   end if
   deallocate (identifier)
 end subroutine compare_tree_check_kingraph
```

Then the graphs of the entry are checked.

⟨*Cascades2: compare tree entry: TBP*⟩+≡

      deallocate (tmp_ptr)
    end subroutine rebuild_graph_entry
  end subroutine compare_tree_entry_check_kingraph
```

The grove to which a completed `kingraph` will be added is determined by the entries of `grove_prop`. We use another list type (linked list) to arrange the groves. Each `grove` contains again a linked list of `kingraphs`.

⟨*Cascades2: types*⟩+≡
```
    type :: grove_t
      type (grove_prop_t) :: grove_prop
      type (grove_t), pointer :: next => null ()
      type (kingraph_t), pointer :: first => null ()
      type (kingraph_t), pointer :: last => null ()
      type (compare_tree_t) :: compare_tree
     contains
     ⟨Cascades2: grove: TBP⟩
    end type grove_t
```

Container for a pointer of type grove_t:

⟨*Cascades2: types*⟩+≡
```
    type :: grove_ptr_t
       type (grove_t), pointer :: grove => null ()
    end type grove_ptr_t
```

⟨*Cascades2: grove: TBP*⟩≡
```
    procedure :: final => grove_final
```
⟨*Cascades2: procedures*⟩+≡
```
    subroutine grove_final (grove)
      class(grove_t), intent(inout) :: grove
      grove%first => null ()
      grove%last  => null ()
      grove%next => null ()
    end subroutine grove_final
```

This is the list type:

⟨*Cascades2: types*⟩+≡
```
    type :: grove_list_t
      type (grove_t), pointer :: first => null ()
     contains
     ⟨Cascades2: grove list: TBP⟩
    end type grove_list_t
```

⟨*Cascades2: grove list: TBP*⟩≡
```
    procedure :: final => grove_list_final
```
⟨*Cascades2: procedures*⟩+≡
```
    subroutine grove_list_final (list)
      class(grove_list_t), intent(inout) :: list
      class(grove_t), pointer :: current
      do while (associated (list%first))
         current => list%first
         list%first => list%first%next
         call current%final ()
         deallocate (current)
      end do
    end subroutine grove_list_final
```

19.14.9 The feyngraph set

The fundament of the module is the public type `feyngraph_set_t`. It is not only a linked list of all `feyngraphs` but contains an array of all particle properties (`particle`), an `f_node_list` and a pointer of the type `grove_list_t`, since several `feyngraph_sets` can share a common `grove_list`. In addition it keeps the data which unambiguously specifies the process, as well as the model which provides information which allows us to choose between equivalent subtrees or complete `kingraphs`.

⟨*Cascades2: public*⟩+≡
```
    public :: feyngraph_set_t
```

⟨*Cascades2: types*⟩+≡
```
    type :: feyngraph_set_t
       type (model_data_t), pointer :: model => null ()
       type(flavor_t), dimension(:,:), allocatable :: flv
       integer :: n_in = 0
       integer :: n_out = 0
       integer :: process_type = DECAY
       type (phs_parameters_t) :: phs_par
       logical :: fatal_beam_decay = .true.
       type (part_prop_t), dimension (:), pointer :: particle => null ()
       type (f_node_list_t) :: f_node_list
       type (feyngraph_t), pointer :: first => null ()
       type (feyngraph_t), pointer :: last => null ()
       integer :: n_graphs = 0
       type (grove_list_t), pointer :: grove_list => null ()
       logical :: use_dag = .true.
       type (dag_t), pointer :: dag => null ()
       type (feyngraph_set_t), dimension (:), pointer :: fset => null ()
     contains
     ⟨Cascades2: feyngraph set: TBP⟩
    end type feyngraph_set_t
```

This final procedure contains calls to all other necessary final procedures.

⟨*Cascades2: feyngraph set: TBP*⟩≡
```
    procedure :: final => feyngraph_set_final
```

⟨*Cascades2: procedures*⟩+≡
```

            deallocate (set%dag)
         end if
      end if
   end subroutine feyngraph_set_final
```

19.14.10   Construct the feyngraph set

We construct the feyngraph_set from an input file. Therefore we pass a unit to
feyngraph_set_build. The parsing subroutines are chosen depending on the
value of use_dag. In the DAG output, which is the one that is produced by
default, we have to work on a string of one line, where the lenght of this string
becomes larger the more particles are involved in the process. The other output
(which is now only used in a unit test) contains one Feynman diagram per line
and each line starts with an open parenthesis so that we read the file line per
line and create a feyngraph for every line. Only after this, nodes are created.
In both decay and scattering processes the diagrams are represented like in a
decay process, i.e. in a scattering process one of the incoming particles appears
as an outgoing particle.

⟨*Cascades2: feyngraph set: TBP*⟩+≡
```
   procedure :: build => feyngraph_set_build
```

⟨*Cascades2: procedures*⟩+≡
```
   subroutine feyngraph_set_build (feyngraph_set, u_in)
     class (feyngraph_set_t), intent (inout) :: feyngraph_set
     integer, intent (in) :: u_in

```

```
      end subroutine feyngraph_set_build
```

Read the string from the file. The output which is produced by O'Mega contains the DAG in a factorised form as a long string, distributed over several lines (in addition, in the case of a scattering process, it contains a similar string for the same process, but with the other incoming particle as the root of the tree structure). In general, such a file can contain many of these strings, belonging to different process components. Therefore we first have to find the correct position of the string for the process in question. Therefore we look for a line containing a pair of colons, in which case the line contains a process string. Then we check if the process string describes the correct process, which is done by checking for all the incoming and outgoing particle names. If the process is correct, the dag output should start in the following line. As long as we do not find the correct process string, we continue searching. If we reach the end of the file, we rewind the unit once, and repeat searching. If the process is still not found, there must be some sort of error.

⟨*Cascades2: dag: TBP*⟩≡
```
      procedure :: read_string => dag_read_string
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine dag_read_string (dag, u_in, flv)

           call msg_bug ("Process string not found in O'Mega input file.")
    end subroutine dag_read_string
```

The output of factorized Feynman diagrams which is created by O'Mega for a given process could in principle be written to a single line in the file. This can

however lead to different problems with different compilers as soon as such lines become too long. This is the reason why the line is cut into smaller pieces. This means that a new line starts after each vertical bar. For this long string the type dag_string_t has been introduced. In order to read the file quickly into such a dag_string we use another type, dag_chain_t which is a linked list of such dag_strings. This has the advantage that we do not have to recreate a new dag_string for every line which has been read from file. Only in the end of this operation we compress the list of strings to a single string, removing useless dag_tokens, such as blanc space tokens. This subroutine reads all lines starting from the position in the file the unit is connected to, until no backslash character is found at the end of a line (the backslash means that the next line also belongs to the current string).

⟨*Cascades2: parameters*⟩+≡
```
    integer, parameter :: BUFFER_LEN = 1000
    integer, parameter :: STACK_SIZE = 100
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine fds_file_get_line (u, string)
      integer, intent (in) :: u
      type (dag_string_t), intent (out) :: string
      type (dag_chain_t) :: chain
      integer :: string_size, current_len
      character (len=BUFFER_LEN) :: buffer
      integer :: fragment_len
      integer :: stat
      current_len = 0
      stat = 0
      string_size = 0
      do while (stat == 0)
         read (unit=u, fmt='(A)', iostat=stat) buffer
         if (stat /= 0) exit
         fragment_len = len_trim (buffer)
         if (fragment_len == 0) then
            exit
         else if (buffer (fragment_len:fragment_len) == BACKSLASH_CHAR) then
            fragment_len = fragment_len - 1
         end if
         call chain%append (buffer(:fragment_len))
         if (buffer(fragment_len+1:fragment_len+1) /= BACKSLASH_CHAR) exit
      enddo
      if (associated (chain%first)) then
         call chain%compress ()
         string = chain%first
         call chain%final ()
      end if
    end subroutine fds_file_get_line
```

We check, if the process string which has been read from file corresponds to the process for which we want to extract the Feynman diagrams.

```

19.14.11   Particle properties

This subroutine initializes a model instance with the Standard Model data. It is only relevant for a unit test. We do not have to care about the model initialization in this module because the `model` is passed to `feyngraph_set_generate` when it is called.

Initialize a `part_prop` object by passing a `particle_label`, which is simply the

particle name. `part_prop` should be part of the `particle` array of `feyngraph_set`. We use the `model` of `feyngraph_set` to obtain the relevant data of the particle which is needed to find `phase_space` parametrizations. When a `part_prop` is initialized, we add and initialize also the corresponding anti- particle `part_prop` if it is not yet in the array.

⟨*Cascades2: part prop: TBP*⟩+≡

         enddo
      end if
    end subroutine part_prop_init
```

This subroutine assigns to a node the particle properties. Since these properties do not change and are simply read from the model file, we use pointers to the elements of the `particle` array of the `feyngraph_set`. If there is no corresponding array element, we have to initialize the first empty element of the array.

!!! in the process definition, we revert this here. An exception is the first particle
!!! in the parsable DAG output
  node%particle => node%particle%anti
end subroutine f_node_assign_particle_properties
```

From the output of a Feynman diagram (in the non-factorized output) we need
to find out how many daughter nodes would be required to reconstruct it cor-
rectly, to make sure that we keep only those **feyngraphs** which are constructed
solely on the basis of the 3-vertices which are provided by the model. The num-
ber of daughter particles can easily be determined from the syntax of O'Mega's
output: The particle which appears before the colon ':' is the mother particle.
The particles or subtrees (i.e. whole parentheses) follow after the colon and are
separated by commas.

        end if
    end if
  end if
end function get_n_daughters
```

19.14.12   Reconstruction of trees

The reconstruction of a tree or subtree with the non-factorized input can be done recursively, i.e. we first find the root of the tree in the string and create an f_node. Then we look for daughters, which in the string appear either as single particles or subtrees (which are of the same form as the tree which we want to reconstruct. Therefore the subroutine can simply be called again and again until there are no more daughter nodes to create. When we meet a vertex which requires more than two daughter particles, we stop the recursion and disable the node using its keep variable. Whenever a daughter node is not kept, we do not keep the mother node as well.

⟨*Cascades2: procedures*⟩+≡
```
recursive subroutine node_construct_subtree_rec (feyngraph_set, &
    feyngraph, subtree_string, mother_node)
  type (feyngraph_set_t), intent (inout) :: feyngraph_set
  type (feyngraph_t), intent (inout) :: feyngraph

end if
if (.not. mother_node%keep) then
   feyngraph%keep = .false.
end if
end subroutine node_construct_subtree_rec
```

When the non-factorized version of the O'Mega output is used, the `feyngraph` is reconstructed from the contents of its `string_t` variable `omega_feyngraph_output`. This can be used for the recursive reconstruction of the tree of `k_nodes` with `node_construct_subtree_rec`.

⟨*Cascades2: procedures*⟩+≡

```
subroutine feyngraph_construct (feyngraph_set, feyngraph)
  type (feyngraph_set_t), intent (inout) :: feyngraph_set
  type (feyngraph_t), pointer, intent (inout) :: feyngraph
  call node_construct_subtree_rec (feyngraph_set, feyngraph, &
        char(feyngraph%omega_feyngraph_output), feyngraph%root)
  feyngraph%n_nodes = feyngraph%root%n_subtree_nodes
end subroutine feyngraph_construct
```

We introduce another node type, which is called **dag_node_t** and is used to reproduce the dag structure which is represented by the input. The **dag_nodes** can have several combinations of daughters 1 and 2. The **dag** type contains an array of **dag_nodes** and is only used for the reconstruction of **feyngraphs** which are factorized as well, but in the other direction as the original output. This means in particular that the outgoing particles in the output file (which there can appear many times) exist only once as **f_nodes**. To represent combinations of daughters and alternatives (options), we further use the types **dag_options_t** and **dag_combination_t**. The **dag_nodes**, **dag_options** and **dag_combinations** correspond to a substring of the string which has been read from file (and transformed into an object of type **dag_string_t**, which is simply another compact representation of this string), or a modified version of this substring. The aim is to create only one object for a given substring, even if it appears several times in the original string and then create trees of **f_nodes**, which build up the **feyngraph**, such that as many **f_nodes** as possible can be reused. An outgoing particle (always interpreting the input as a decay) is called a **leaf** in the context of a **dag**.

⟨*Cascades2: types*⟩+≡
```
type :: dag_node_t
  integer :: string_len
  type (dag_string_t) :: string
  logical :: leaf = .false.

        if (associated (dag_node%f_node(i)%node)) then
           call dag_node%f_node(i)%node%final ()
           deallocate (dag_node%f_node(i)%node)
        end if
     enddo
     deallocate (dag_node%f_node)
```

2596

```
        end if
    end subroutine dag_node_final
```

Whenever there are more than one possible subtrees (represented by a dag_node) or combinations of subtrees to daughters (represented by dag_combination_t), we use the type dag_options_t. In the syntax of the factorized output, options are listed within curly braces, separated by horizontal bars.

⟨*Cascades2: types*⟩+≡
```
    type :: dag_options_t
       integer :: string_len
       type (dag_string_t) :: string
       type (f_node_ptr_t), dimension (:), allocatable :: f_node_ptr1
       type (f_node_ptr_t), dimension (:), allocatable :: f_node_ptr2
     contains
       ⟨Cascades2: dag options: TBP⟩
    end type dag_options_t
```

⟨*Cascades2: dag options: TBP*⟩≡
```
    procedure :: final => dag_options_final
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine dag_options_final (dag_options)
      class (dag_options_t), intent (inout) :: dag_options
      integer :: i
      call dag_options%string%final ()
      if (allocated (dag_options%f_node_ptr1)) then
         do i=1, size (dag_options%f_node_ptr1)
            dag_options%f_node_ptr1(i)%node => null ()
         enddo
         deallocate (dag_options%f_node_ptr1)
      end if
        if (allocated (dag_options%f_node_ptr2)) then
         do i=1, size (dag_options%f_node_ptr2)
            dag_options%f_node_ptr2(i)%node => null ()
         enddo
         deallocate (dag_options%f_node_ptr2)
      end if
    end subroutine dag_options_final
```

A pair of two daughters (which can be dag_nodes or dag_options) is represented by the type dag_combination_t. In the original string, a dag_combination appears between parentheses, which contain a comma, but not a colon. If we find a colon between these parentheses, it is a a dag_node instead.

⟨*Cascades2: types*⟩+≡
```
    type :: dag_combination_t
       integer :: string_len
       type (dag_string_t) :: string
       integer, dimension (2) :: combination
       type (f_node_ptr_t), dimension (:), allocatable :: f_node_ptr1
       type (f_node_ptr_t), dimension (:), allocatable :: f_node_ptr2
     contains
       ⟨Cascades2: dag combination: TBP⟩
```

```
        end type dag_combination_t
```

⟨*Cascades2: dag combination: TBP*⟩≡
```
    procedure :: final => dag_combination_final
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine dag_combination_final (dag_combination)
      class (dag_combination_t), intent (inout) :: dag_combination
      integer :: i
      call dag_combination%string%final ()
      if (allocated (dag_combination%f_node_ptr1)) then
         do i=1, size (dag_combination%f_node_ptr1)
            dag_combination%f_node_ptr1(i)%node => null ()
         enddo

            end if
            if (allocated (dag%combination)) then
               do i=1, size (dag%combination)
                  call dag%combination(i)%final ()
               enddo
               deallocate (dag%combination)
            end if
         end subroutine dag_final
```

We construct the DAG from the given `dag_string` which is modified several
times so that in the end the remaining string corresponds to a simple `dag_node`,
the root of the factorized tree. This means that we first identify the leaves,
i.e. outgoing particles. Then we identify `dag_nodes`, `dag_combinations` and
`options` until the number of these objects does not change any more. Identifying
means that we add a corresponding object to the array (if not yet present), which
can be identified with the corresponding substring, and replace the substring
in the original `dag_string` by a `dag_token` of the corresponding type (in the
char output of this token, this corresponds to a place holder like e.g. '¡O23¿'
which in this particular case corresponds to an option and can be found at the
position 23 in the array). The character output of the substrings turns out to
be very useful for debugging.

```

Identify `dag_nodes` and `dag_combinations`. Leaves are simply nodes (i.e. of type NODE_TK) where only one bit in the bincode is set. The `dag_nodes` and `dag_combinations` have in common that they are surrounded by parentheses. There is however a way to distinguish between them because the corresponding substring contains a colon (or `dag_token` with type COLON_TK) if it is a `dag_node`. Otherwise it is a `dag_combination`. The string of the `dag_node` or `dag_combination` should not contain curly braces, because these correspond to `dag_options` and should be identified before.

For a given `dag_node` we want to create all `f_nodes`. If the node is not a leaf,
it contains in its string placeholders for options or combinations. For these
objects there are similar subroutines which are needed here to obtain the sets of
daughter nodes. If the `dag_node` is a leaf, it corresponds to an external particle
and the token contains the particle name.

In dag_options_make_f_nodes_single we obtain all f_nodes for dag_nodes
which correspond to a set of rival subtrees or nodes, which is the first possibil-
ity for which dag_options can appear. In dag_options_make_f_nodes_pair the
options are rival pairs (daughter1, daughter2). Therefore we have to pass two
allocatable arrays of type f_node_ptr_t to the subroutine.

We create all combinations of daughter f_nodes for a combination. In the combination each daughter can be either a single dag_node or dag_options which are a set of single dag_nodes. Therefore, we first create all possible f_nodes for daughter1, then all possible f_nodes for daughter2. In the end we combine all daughter1 nodes with all daughter2 nodes.

Here we create the `feyngraphs`. After the construction of the `dag` the remaining
`dag_string` should contain a token for a single `dag_node` which corresponds to
the roots of the `feyngraphs`. Therefore we make all `f_nodes` for this `dag_node`
and create a `feyngraph` for each `f_node`. Note that only 3-vertices are accepted.
All other vertices are rejected. The starting point is the last dag node which
has been added to the list, since this corresponds to the root of the tree. Is is
important to understand that the structure of feyngraphs is not the same as
the structure of the dag which is read from file, because for the calculations
which are performed in this module we want to reuse the nodes for the outgoing
particles, which means that they appear only once. In O'Mega's output, it is
the first incoming particle which appears only once and the outgoing particles
appear many times. This transition is incorporated in the subroutines which
create `f_nodes` from the different dag objects.

    end subroutine k_node_make_nonresonant_copy
```

For a given **feyngraph** we create all possible **kingraphs**. Here we use existing **k_nodes** which have already been created when the mapping calculations of the pure s-channel subgraphs are performed. The nodes for the incoming particles or the nodes on the t-line will have to be created in all cases because they are not used in several graphs. To obtain the existing **k_nodes**, we use the subroutine **k_node_init_from_f_node** which itself uses **f_node_list_get_nodes** to obtain all active **k_nodes** in the **k_node_list** of the **f_node**. The created **kingraphs** are attached to the linked list of the **feyngraph**. For scattering processes we have to split up the t-line, because since all graphs are represented as a decay, different nodes can share daughter nodes. This happens also for the t-line or the incoming particle which appears as an outgoing particle. For the **t_line** or **incoming** nodes we do not want to recycle nodes but rather create a copy of this line for each **kingraph**.

      end if
   end if
end subroutine k_node_init_from_f_node
```

The graphs resulting from k_node_init_from_f_node are fine if they are used only in one direction. This is however not the case when one wants to invert the graphs, i.e. take the other incoming particle of a scattering process as the decaying particle, because the outgoing f_nodes (and hence also the k_nodes) exist only once. This problem is solved here by creating a distinct t-line for each of the graphs. The following subroutine disentangles the data structure by

2615

creating new nodes such that the different t-lines are not connected any more.

⟨*Cascades2: procedures*⟩+≡

```fortran
recursive subroutine split_up_t_lines (t_node)
  type (k_node_ptr_t), dimension(:), intent (inout) :: t_node
  type (k_node_t), pointer :: ref_node => null ()
  type (k_node_t), pointer :: ref_daughter => null ()
  type (k_node_t), pointer :: new_daughter => null ()
  type (k_node_ptr_t), dimension(:), allocatable :: t_daughter
  integer :: ref_daughter_index
  integer :: i, j
  allocate (t_daughter (size (t_node)))
  do i=1, size (t_node)
    ref_node => t_node(i)%node
    if (associated (ref_node%daughter1) .and. associated (ref_node%daughter2)) then
      ref_daughter => null ()
      if (ref_node%daughter1%incoming .or. ref_node%daughter1%t_line) then
        ref_daughter => ref_node%daughter1
        ref_daughter_index = 1
      else if (ref_node%daughter2%incoming .or. ref_node%daughter2%t_line) then
        ref_daughter => ref_node%daughter2
        ref_daughter_index = 2
      end if
      do j=1, size (t_daughter)
        if (.not. associated (t_daughter(j)%node)) then
          t_daughter(j)%node => ref_daughter
          exit
        else if (t_daughter(j)%node%index == ref_daughter%index) then
          new_daughter => null ()
          call ref_daughter%f_node%k_node_list%add_entry (new_daughter, recycle=.false.)
          new_daughter = ref_daughter
          new_daughter%daughter1 => ref_daughter%daughter1
          new_daughter%daughter2 => ref_daughter%daughter2
          if (ref_daughter_index == 1) then
            ref_node%daughter1 => new_daughter
          else if (ref_daughter_index == 2) then
            ref_node%daughter2 => new_daughter
          end if
          ref_daughter => new_daughter
        end if
      enddo
    else
      return
    end if
  enddo
  call split_up_t_lines (t_daughter)
  deallocate (t_daughter)
end subroutine split_up_t_lines
```

This subroutine sets the `inverse_daughters` of a `k_node`. If we invert a `kingraph` such that not the first but the second incoming particle appears as the root of the tree, the `incoming` and `t_line` particles obtain other daughters. These are the former mother node and the sister node `s_daughter`. Here we set only the pointers for the `inverse_daughters`. The inversion happens in `kingraph_make_inverse_copy`

and `node_inverse_deep_copy`.

⟨*Cascades2: procedures*⟩+≡
```
subroutine kingraph_set_inverse_daughters (kingraph)
  type (kingraph_t), intent (inout) :: kingraph
  type (k_node_t), pointer :: mother
  type (k_node_t), pointer :: t_daughter
  type (k_node_t), pointer :: s_daughter
  mother => kingraph%root
  do while (associated (mother))
     if (associated (mother%daughter1) .and. &
         associated (mother%daughter2)) then
        if (mother%daughter1%t_line .or. mother%daughter1%incoming) then
           t_daughter => mother%daughter1; s_daughter => mother%daughter2
        else if (mother%daughter2%t_line .or. mother%daughter2%incoming) then
           t_daughter => mother%daughter2; s_daughter => mother%daughter1
        else
           exit
        end if
        t_daughter%inverse_daughter1 => mother
        t_daughter%inverse_daughter2 => s_daughter
        mother => t_daughter
     else
        exit
     end if
  enddo
end subroutine kingraph_set_inverse_daughters
```

Set the bincode of an `f_node` which corresponds to an external particle. This
is done on the basis of the `particle_label` which is a substring of the input
file. Here it is not the particle name which is important, but the number(s) in
brackets which in general indicate the external particles which are connected
to the current node. This function is however only used for external particles,
so there can either be one or `n_out + 1` particles in the brackets (in the DAG
input file always one, because also for the root there is only a single number).
In all cases we check the number of particles (in the DAG input the numbers
are separated by a slash).

⟨*Cascades2: procedures*⟩+≡
```
function f_node_get_external_bincode (feyngraph_set, f_node) result (bincode)
  type (feyngraph_set_t), intent (in) :: feyngraph_set
  type (f_node_t), intent (in) :: f_node
  integer (TC) :: bincode
  character (len=LABEL_LEN) :: particle_label
  integer :: start_pos, end_pos, n_out_decay
  integer :: n_prt ! for DAG
  integer :: i
  bincode = 0
  if (feyngraph_set%process_type == DECAY) then
     n_out_decay = feyngraph_set%n_out
  else
     n_out_decay = feyngraph_set%n_out + 1
  end if
  particle_label = f_node%particle_label
  start_pos = index (particle_label, '[') + 1
```

```
        end_pos = index (particle_label, ']') - 1
        particle_label = particle_label(start_pos:end_pos)
!!! n_out_decay is the number of outgoing particles in the
!!! O'Mega output, which is always represented as a decay
      if (feyngraph_set%use_dag) then
         n_prt = 1
         do i=1, len(particle_label)
            if (particle_label(i:i) == '/') n_prt = n_prt + 1
         enddo
      else
         n_prt = end_pos - start_pos + 1
      end if
      if (n_prt == 1) then
         bincode = calculate_external_bincode (particle_label, &
               feyngraph_set%process_type, n_out_decay)
      else if (n_prt == n_out_decay) then
         bincode = ibset (0, n_out_decay)
      end if
    end function f_node_get_external_bincode
```

Assign a bincode to an internal node, which is calculated from the bincodes of
`daughter1` and `daughter2`.

⟨*Cascades2: procedures*⟩+≡
```
    subroutine node_assign_bincode (node)
      type (k_node_t), intent (inout) :: node
      if (associated (node%daughter1) .and. associated (node%daughter2) &
            .and. .not. node%incoming) then
         node%bincode = ior(node%daughter1%bincode, node%daughter2%bincode)
      end if
    end subroutine node_assign_bincode
```

Calculate the `bincode` from the number in the brackets of the `particle_label`,
if the node is external. For the root in the non-factorized output, this is cal-
culated directly in f_node_get_external_bincode because in this case all the
other external particle numbers appear between the brackets.

⟨*Cascades2: procedures*⟩+≡
```
    function calculate_external_bincode (label_number_string, process_type, n_out_decay) result (bin
      character (len=*), intent (in) :: label_number_string
      integer, intent (in) :: process_type
      integer, intent (in) :: n_out_decay
      character :: number_char
      integer :: number_int
      integer (kind=TC) :: bincode
      bincode = 0
      read (label_number_string, fmt='(A)') number_char
!!! check if the character is a letter (A,B,C,...) or a number (1...9)
!!! numbers 1 and 2 are special cases
      select case (number_char)
      case ('1')
         if (process_type == SCATTERING) then
            number_int = n_out_decay + 3
         else
            number_int = n_out_decay + 2
```

2618

```
            end if
         case ('2')
            if (process_type == SCATTERING) then
               number_int = n_out_decay + 2
            else
               number_int = 2
            end if
         case ('A')
            number_int = 10
         case ('B')
            number_int = 11
         case ('C')
            number_int = 12
         case ('D')
            number_int = 13
         case default
            read (number_char, fmt='(I1)') number_int
         end select
         bincode = ibset (bincode, number_int - process_type - 1)
      end function calculate_external_bincode
```

19.14.13   Mapping calculations

Once a k_node and its subtree nodes have been created, we can perform the kinematical calculations and assign mappings, depending on the particle properties and the results for the subtree nodes. This could in principle be done recursively, calling the procedure first for the daughter nodes and then perform the calculations for the actual node. But for parallization and comparing the nodes, this will be done simultaneously for all nodes with the same number of subtree nodes, and the number of subtree nodes increases, starting from one, in steps of two. The actual mapping calculations are done in complete analogy to cascades.

⟨*Cascades2: procedures*⟩+≡
```
      subroutine node_assign_mapping_s (feyngraph, node, feyngraph_set)
        type (feyngraph_t), intent (inout) :: feyngraph
        type (k_node_t), intent (inout) :: node
        type (feyngraph_set_t), intent (inout) :: feyngraph_set
        real(default) :: eff_mass_sum
        logical :: keep
        if (.not. node%mapping_assigned) then
           if (node%particle%mass > feyngraph_set%phs_par%m_threshold_s) then
              node%effective_mass = node%particle%mass
           end if
           if (associated (node%daughter1) .and. associated (node%daughter2)) then
              if (.not. (node%daughter1%keep .and. node%daughter2%keep)) then
                 node%keep = .false.; return
              end if

      end if
      if (kingraph%keep) kingraph%tree = kingraph%root%subtree
    end subroutine kingraph_compute_mappings_t_line
```

Perform the kinematical calculations and mapping assignment for a node which
is either incoming or t_line. This is done recursively, going first to the daughter
node which has this property. Therefore we first set the pointer t_node to
this daughter node and s_node to the other one. The mapping determination
happens again in the same way as in cascades.

⟨*Cascades2: procedures*⟩+≡

After all pure s-channel subdiagrams have already been created from the corresponding **f_nodes** and mappings have been determined for their nodes, we complete the calculations here. In a first step, the **kingraphs** have to be created on the basis of the existing **k_nodes**, which means in particular that a **feyngraph** can give rise to several **kingraphs** which will all be attached to the linked list of the **feyngraph**. The calculations which remain are of different kinds for decay and scattering processes. In a decay process the kinematical calculations have to be done for the **root** node. In a scattering process, after the creation of **kingraphs** in the first step, there will be only **kingraphs** with the first incoming particle as the **root** of the tree. For these graphs the **inverse** variable has the value **.false.**. Before performing any calculations on these graphs we make a so-called inverse copy of the graph (see below), which will also be attached to the linked list. Since the s-channel subgraph calculations have already been completed, only the t-line computations remain.

Here we control the mapping calculations for the nodes of s-channel subgraphs.
We start with the nodes with the smallest number of subtree nodes and always
increase this number by two because nodes have exactly zero or two daughter
nodes. We create the k_nodes using the k_node_list of each f_node. The
number of nodes which have to be created depends of the number of existing
daughter nodes, which means that we have to create a node for each combination
of existing and valid (the ones which we keep) daughter nodes. If the node
corresponds to an external particle, we create only one node, since there are
no daughter nodes. If the particle is not external and the daughter f_nodes do
not contain any valid k_nodes, we do not create a new k_nodes either. When
the calculations for all nodes with the same number of subtree nodes have been
completed, we compare the valid nodes to eliminate equivalences (see below).

19.14.14   Fill the grove list

Find the `grove` within the `grove_list` for a `kingraph` for which the kinematical calculations and mapping assignments have been completed. The `groves` are defined by the `grove_prop` entries and the value of the resonance hash (`res_hash`). Whenever a matching grove does not exist, we create one. In a first step we consider only part of the grove properties (see `grove_prop_match`) and the resonance hash is ignored, which leads to a preliminary grove list. In the end all numbers in `grove_prop` as well as the resonance hash are compared, i.e. we create a new `grove_list`.

⟨*Cascades2: grove list: TBP*⟩+≡
```
    procedure :: get_grove => grove_list_get_grove
```

⟨*Cascades2: procedures*⟩+≡
```
    subroutine grove_list_get_grove (grove_list, kingraph, return_grove, preliminary)
      class (grove_list_t), intent (inout) :: grove_list
      type (kingraph_t), intent (in), pointer :: kingraph
      type (grove_t), intent (inout), pointer :: return_grove
      logical, intent (in) :: preliminary
      type (grove_t), pointer :: current_grove
      return_grove => null ()
      if (.not. associated(grove_list%first)) then
         allocate (grove_list%first)
         grove_list%first%grove_prop = kingraph%grove_prop
         return_grove => grove_list%first
         return
      end if
      current_grove => grove_list%first
      do while (associated (current_grove))
```

```
            if ((preliminary .and. (current_grove%grove_prop .match. kingraph%grove_prop)) .or. &
                (.not. preliminary .and. current_grove%grove_prop == kingraph%grove_prop)) then
                return_grove => current_grove
                exit
            else if (.not. associated (current_grove%next)) then
                allocate (current_grove%next)
                current_grove%next%grove_prop = kingraph%grove_prop
                if (size (kingraph%tree%bc) < 9) &

         end if
      enddo
      if (associated (feyngraph%kin_first)) then
         current_kingraph => feyngraph%kin_first
         do while (associated (current_kingraph%next))
            if (current_kingraph%next%keep) then
               add_kingraph => current_kingraph%next
               current_kingraph%next => current_kingraph%next%next
               add_kingraph%next => null ()
               call grove_list%add_kingraph (kingraph=add_kingraph, &
                    preliminary=.true., check=.true., model=model)
            else
               current_kingraph => current_kingraph%next
            end if
         enddo
      end if
    end subroutine grove_list_add_feyngraph
```

Compare two `grove_prop` objects. The `.match.` operator is used for preliminary groves in which the `kingraphs` share only the 3 numbers `n_resonances`, `n_log_enhanced` and `n_t_channel`. These groves are only used for comparing the kingraphs, because only graphs within these preliminary groves can be equivalent (the numbers which are compared here are unambigously fixed by the combination of mappings in these channels).

⟨*Cascades2: interfaces*⟩+≡
```
    interface operator (.match.)
       module procedure grove_prop_match
    end interface operator (.match.)
```

⟨*Cascades2: procedures*⟩+≡
```
    function grove_prop_match (grove_prop1, grove_prop2) result (gp_match)
      type (grove_prop_t), intent (in) :: grove_prop1
```

```
    type (grove_prop_t), intent (in) :: grove_prop2
    logical :: gp_match
    gp_match = (grove_prop1%n_resonances == grove_prop2%n_resonances) &
         .and. (grove_prop1%n_log_enhanced == grove_prop2%n_log_enhanced) &
         .and. (grove_prop1%n_t_channel == grove_prop2%n_t_channel)
  end function grove_prop_match
```

The equal operator on the other hand will be used when all valid `kingraphs`
have been created and mappings have been determined, to split up the existing
(preliminary) grove list, i.e. to create new groves which are determined by all
entries in `grove_prop_t`.

⟨*Cascades2: interfaces*⟩+≡
```
    interface operator (==)
       module procedure grove_prop_equal
    end interface operator (==)
```

⟨*Cascades2: procedures*⟩+≡
```
    function grove_prop_equal (grove_prop1, grove_prop2) result (gp_equal)
      type (grove_prop_t), intent (in) :: grove_prop1
      type (grove_prop_t), intent (in) :: grove_prop2
      logical :: gp_equal
      gp_equal = (grove_prop1%res_hash == grove_prop2%res_hash) &
           .and. (grove_prop1%n_resonances == grove_prop2%n_resonances) &
           .and. (grove_prop1%n_log_enhanced == grove_prop2%n_log_enhanced) &
           .and. (grove_prop1%n_off_shell == grove_prop2%n_off_shell) &

    end function grove_prop_equal
```

19.14.15   Remove equivalent channels

Here we define the equivalence condition for completed `kingraphs`. The aim is
to keep those `kingraphs` which describe the strongest peaks of the amplitude.
The `bincodes` and `mappings` have to be the same for an equivalence, but the
`pdgs` can be different. At the same time we check if the trees are exacly the
same (up to the sign of pdg codes) in which case we do not keep both of them.
This can be the case when the incoming particles are the same or their mutual
anti-particles and there are no t-channel lines in the Feynman diagram to which
the kingraph belongs.

⟨*Cascades2: parameters*⟩+≡

            end if
        end function kingraph_eqv
```

Select between two `kingraphs` which fulfill the equivalence condition above.
This is done by comparing the `pdg` values of the `tree` for increasing bincode.
If the particles are different at some place, we usually choose the one which
would be returned first by the subroutine `match_vertex` of the model for the
daughter `pdg` codes. Since we work here only on the basis of the the `trees` of the
completed `kingraphs`, we have to use the `bc` array to determine the positions
of the daughter nodes' entries in the array. The graph which has to be kept
should correspond to the stronger peak at the place which is compared.

              end if
           end if
        enddo
     end if
   end subroutine kingraph_select
```

At the beginning we do not care about the resonance hash, but only about part of the grove properties, which is defined in grove_prop_match. In these resulting preliminary groves the kingraphs can be equivalent, i.e. we do not have to compare all graphs with each other but only all graphs within each of these preliminary groves. In the end we create a new grove list where the grove properties of the kingraphs within a grove have to be exactly the same and

in addition the groves are distinguished by the resonance hash values. Here the kingraphs are not compared any more, which means that the number of channels is not reduced any more.

   end function get_particle_name
```

19.14.17 Invert a graph

All Feynman diagrams given by O'Mega look like a decay. The `feyngraph`
which is constructed from this output also looks like a decay, where one of
the incoming particles is the decaying particle (or the root of the tree). The
calculations can in principle be done on this data structure. However, it is
also performed with the other incoming particle as the root. The first part
of the calculation is the same for both cases. For the second part we need to
transform/turn the graphs such that the other incoming particle becomes the
root. This is done by identifying the incoming particles from the O'Mega output
(the first one is simply the root of the existing tree, the second contains [2]
in the `particle_label`) and the nodes/particles which connect both incoming
particles (here we set `t_line = .true.`). At the same time we set the pointers
`inverse_daughter1` and `inverse_daughter2` for the corresponding node, which
point to the mother node and the other daughter of the mother node; these will
be the daughters of the node in the inverted `feyngraph`.

Recursively deep-copy nodes, but along the t-line the inverse daughters become
the new daughters. We need a deep copy only for the `incoming` or `t_line` nodes.
For the other nodes (of s-channel subgraphs) we set only pointers to the existing
nodes of the non-inverted graph.

      call feyngraph_set_find_phs_parametrizations(feyngraph_set)
    end subroutine feyngraph_set_generate_single
```

Find the phase space parametrizations. We start with the computation of pure
s-channel subtrees, i.e. we determine mappings and compare subtrees in order
to reduce the number of channels. This can be parallelized easily. When all
s-channel k_nodes exist, the possible kingraphs are created using these nodes
and we determine mappings for t-channel nodes.

⟨*Cascades2: procedures*⟩+≡

Chapter 20

VEGAS Integration

The backbone integrator of WHIZARD is a object-oriented implemetation of
the VEGAS algorithm.

⟨`vegas.f90`⟩≡
  ⟨*File header*⟩

  ```
  module vegas
  ```
  ⟨*Use kinds*⟩

  ⟨*vegas: modules*⟩

  ⟨*Standard module head*⟩

  ⟨*vegas: public*⟩

  ⟨*vegas: parameters*⟩

  ⟨*vegas: types*⟩

  ⟨*vegas: interfaces*⟩

  ```
  contains
  ```

  ⟨*vegas: procedures*⟩

  ```
  end module vegas
  ```

⟨*vegas: modules*⟩≡
```
    use diagnostics
    use io_units
    use format_utils, only: write_indent
    use format_defs, only: FMT_17
    use rng_base, only: rng_t
    use rng_stream, only: rng_stream_t
```

MPI Module.

⟨*MPI: vegas: modules*⟩≡
```
    use mpi_f08 !NODEP!
```

20.1 Integration modes

VEGAS operates in three different modes: `vegas_mode_importance_only`, `vegas_mode_importance` or `vegas_mode_stratified`. The default mode is `vegas_mode_importance`, where the algorithm decides whether if it is possible to use importance sampling or stratified sampling. In low dimensions VEGAS uses strict stratified sampling.

⟨*vegas: parameters*⟩≡
```
    integer, parameter, public :: VEGAS_MODE_IMPORTANCE = 0, &
        & VEGAS_MODE_STRATIFIED = 1, VEGAS_MODE_IMPORTANCE_ONLY = 2
```

20.2 Type: vegas_func_t

We define a abstract `func` type which only gives an interface to an `evaluate` procedure. The inside of implementation and also the optimization of are not a concern of the `vegas` implementation.

⟨*vegas: public*⟩≡
```
    public :: vegas_func_t
```

⟨*vegas: types*⟩≡
```
    type, abstract :: vegas_func_t
       !
     contains
       procedure(vegas_func_evaluate), deferred, pass, public :: evaluate
    end type vegas_func_t
```

The only procedure called in `vegas` is `vegas_func_evaluate`. It takes a real value `x` and returns a real value `f`.

⟨*vegas: interfaces*⟩≡
```
    abstract interface
       real(default) function vegas_func_evaluate (self, x) result (f)
         import :: default, vegas_func_t
         class(vegas_func_t), intent(inout) :: self
         real(default), dimension(:), intent(in) :: x
       end function vegas_func_evaluate
    end interface
```

20.3 Type: vegas_config_t

We store the complete configuration in a transparent container. The `vegas_config_t` object inside VEGAS must not be directly accesible. We provide a get method which returns a copy of the `vegas_config_t` object.

Apart from the options which can be set by the constructor of `vegas_t` object, we store the run-time configuration `n_calls`, `calls_per_box`, `n_bins` and `n_boxes`. Those are calculated and set accordingly by VEGAS.

⟨*vegas: public*⟩+≡
```
    public :: vegas_config_t
```

⟨*vegas: types*⟩+≡
```
    type :: vegas_config_t
       integer :: n_dim = 0
       real(default) :: alpha = 1.5
       integer :: n_bins_max = 50
       integer :: iterations = 5
       integer :: mode = VEGAS_MODE_STRATIFIED
       integer :: calls_per_box = 0
       integer :: n_calls = 0
       integer :: n_calls_min = 20
       integer :: n_boxes = 1
       integer :: n_bins = 1
     contains
     ⟨vegas: vegas config: TBP⟩
    end type vegas_config_t
```

Write out the configuration of the grid.

⟨*vegas: vegas config: TBP*⟩≡
```
    procedure, public :: write => vegas_config_write
```

⟨*vegas: procedures*⟩≡
```
    subroutine vegas_config_write (self, unit, indent)
      class(vegas_config_t), intent(in) :: self
      integer, intent(in), optional :: unit
      integer, intent(in), optional :: indent
      integer :: u, ind
      u = given_output_unit (unit)
      ind = 0; if (present (indent)) ind = indent
      call write_indent (u, ind)
      write (u, "(2x,A,I0)") &
           & "Number of dimensions          = ", self%n_dim
      call write_indent (u, ind)
      write (u, "(2x,A," // FMT_17 // ")") &
           & "Adaption power (alpha)        = ", self%alpha

      write (u, "(2x,A,I0)") &
           & "Max. number of bins (per dim.) = ", self%n_bins_max
      call write_indent (u, ind)
      write (u, "(2x,A,I0)") &
           & "Number of iterations          = ", self%iterations
      call write_indent (u, ind)
      write (u, "(2x,A,I0)") &
           & "Mode (stratified or importance) = ", self%mode
      call write_indent (u, ind)
      write (u, "(2x,A,I0)") &
           & "Calls per box                 = ", self%calls_per_box
      call write_indent (u, ind)
      write (u, "(2x,A,I0)") &
           & "Number of calls               = ", self%n_calls
      call write_indent (u, ind)
      write (u, "(2x,A,I0)") &
           & "Min. number of calls          = ", self%n_calls_min
      call write_indent (u, ind)
      write (u, "(2x,A,I0)") &
```

```
      & "Number of bins                 = ", self%n_bins
    call write_indent (u, ind)
    write (u, "(2x,A,I0)") &
          & "Number of boxes                = ", self%n_boxes
  end subroutine vegas_config_write
```

20.4   Type: vegas_grid_t

We provide a simple and transparent grid container. The container can then
later be used, to export the actual grid.

⟨*vegas: public*⟩+≡
```
    public :: vegas_grid_t
```

⟨*vegas: types*⟩+≡
```
    type :: vegas_grid_t
       integer :: n_dim = 1
       integer :: n_bins = 1
       real(default), dimension(:), allocatable :: x_lower
       real(default), dimension(:), allocatable :: x_upper
       real(default), dimension(:), allocatable :: delta_x
       real(default), dimension(:,:), allocatable :: xi
     contains
     ⟨vegas: vegas grid: TBP⟩
    end type vegas_grid_t
```

Initialise grid.

⟨*vegas: interfaces*⟩+≡
```
    interface vegas_grid_t
       module procedure vegas_grid_init
    end interface vegas_grid_t
```

⟨*vegas: procedures*⟩+≡
```
    type(vegas_grid_t) function vegas_grid_init (n_dim, n_bins_max) result (self)
       integer, intent(in) :: n_dim
       integer, intent(in) :: n_bins_max
       self%n_dim = n_dim
       self%n_bins = 1
       allocate (self%x_upper(n_dim), source=1.0_default)
       allocate (self%x_lower(n_dim), source=0.0_default)
       allocate (self%delta_x(n_dim), source=1.0_default)
       allocate (self%xi((n_bins_max + 1), n_dim), source=0.0_default)
    end function vegas_grid_init
```

Output.

⟨*vegas: vegas grid: TBP*⟩≡
```
    procedure, public :: write => vegas_grid_write
```

⟨*vegas: procedures*⟩+≡
```
    subroutine vegas_grid_write (self, unit)
       class(vegas_grid_t), intent(in) :: self
```

```
      integer, intent(in), optional :: unit
      integer :: u, i, j
      u = given_output_unit (unit)
      write (u, descr_fmt) "begin vegas_grid_t"

         do i = 1, self%n_bins + 1
            write (u, double_array2_fmt) i, j, self%xi(i, j)
         end do
      end do
      write (u, descr_fmt) "end xi"
      write (u, descr_fmt) "end vegas_grid_t"
    end subroutine vegas_grid_write
```

Compare two grids, if they match up to an given precision.

⟨*vegas: public*⟩+≡
```
    public :: operator (==)
```

⟨*vegas: interfaces*⟩+≡
```
    interface operator (==)
       module procedure vegas_grid_equal
    end interface operator (==)
```

⟨*vegas: procedures*⟩+≡
```
    logical function vegas_grid_equal (grid_a, grid_b) result (yorn)
      type(vegas_grid_t), intent(in) :: grid_a, grid_b
      yorn = .true.
      yorn = yorn .and. (grid_a%n_dim == grid_b%n_dim)
      yorn = yorn .and. (grid_a%n_bins == grid_b%n_bins)
      yorn = yorn .and. all (grid_a%x_lower == grid_b%x_lower)
      yorn = yorn .and. all (grid_a%x_upper == grid_b%x_upper)
      yorn = yorn .and. all (grid_a%delta_x == grid_b%delta_x)
      yorn = yorn .and. all (grid_a%xi == grid_b%xi)
    end function vegas_grid_equal
```

Resize each bin accordingly to its corresponding weight `w`. Can be used to resize
the grid to a new size of bins or refinement.

2666

The procedure expects two arguments, firstly, **n_bins** and, secondly, the refinement weights **w**. If **n_bins** differs from the internally stored one, we resize the grid under consideration of **w**. If each element of **w** equals one, then the bins are resized preserving their original bin density.

Anytime else, we refine the grid accordingly to **w**.

⟨*vegas: vegas grid: TBP*⟩+≡
```
    procedure, private :: resize => vegas_grid_resize
```

⟨*vegas: procedures*⟩+≡
```
    subroutine vegas_grid_resize (self, n_bins, w)

      end do
    end subroutine vegas_grid_resize
```

Find the probability for a given **x** in the unit hypercube.

For the case **n_bins < N_BINARY_SEARCH**, we utilize linear search which is faster for short arrays. Else we make use of a binary search. Furthermore, we calculate the inverse of the probability and invert the result only at the end (saving some time on division).

Broadcast the grid information. As safety measure, we get the actual grid object from VEGAS (correclty allocated, but for non-root unfilled) and broadcast the root object. On success, we set grid into VEGAS.

We use the non-blocking broadcast routine, because we have to send quite a bunch of integers and reals.

We have to be very careful with **n_bins**, the number of bins can actually change during different iterations. If we reuse a grid, we have to take that, every grid uses the same **n_bins**. We expect, that the number of dimension does not change, which is in principle possible, but will be checked onto in **vegas_set_grid**.

⟨*MPI: vegas: vegas grid: TBP*⟩≡

  end subroutine vegas_grid_broadcast
```

20.5 Type: vegas_result_t

We store the result of the latest iteration(s) in a transparent container. The vegas_result_t object inside VEGAS must not be directly accessible. We export the a copy of the result via a get-method of the vegas_t object.

We store latest event weight in evt_weight and a (possible) evebt weight excess in evt_weight_excess, if the event weight is larger than max_abs_f.

20.6   Type: vegas_t

The VEGAS object contains the methods for integration and grid resize- and re-
finement. We store the grid configuration and the (current) result in transparent
containers alongside with the actual grid and the distribution.

The values of the distribution depend on the chosen mode whether the func-
tion value or the variance is stored. The distribution is used after each iteration
to refine the grid.

⟨*vegas: public*⟩+≡
```
      public :: vegas_t
```

⟨*vegas: types*⟩+≡
```
      type :: vegas_t
         private
         type(vegas_config_t) :: config
         real(default) :: hypercube_volume = 0.
         real(default) :: jacobian = 0.
         real(default), dimension(:, :), allocatable :: d
         type(vegas_grid_t) :: grid
         integer, dimension(:), allocatable :: bin
         integer, dimension(:), allocatable :: box
         type(vegas_result_t) :: result
       contains
       ⟨vegas: vegas: TBP⟩
      end type vegas_t
```

We overload the type constructor of vegas_t which initialises the mandatory
argument n_dim and allocate memory for the grid.

⟨*vegas: interfaces*⟩+≡
```
      interface vegas_t
         module procedure vegas_init
      end interface vegas_t
```

⟨*vegas: procedures*⟩+≡
```

      integer, intent(in) :: n_dim
      integer, intent(in), optional :: n_bins_max
      real(default), intent(in), optional :: alpha
      integer, intent(in), optional :: iterations
      integer, intent(in), optional :: mode
      self%config%n_dim = n_dim
      if (present (alpha)) self%config%alpha = alpha
      if (present (n_bins_max)) self%config%n_bins_max = n_bins_max
      if (present (iterations)) self%config%iterations = iterations
      if (present (mode)) self%config%mode = mode
      self%grid = vegas_grid_t (n_dim, self%config%n_bins_max)
      allocate (self%d(self%config%n_bins_max, n_dim), source=0.0_default)
      allocate (self%box(n_dim), source=1)
      allocate (self%bin(n_dim), source=1)
      self%config%n_bins = 1
      self%config%n_boxes = 1
      call self%set_limits (self%grid%x_lower, self%grid%x_upper)
      call self%reset_grid ()
      call self%reset_result ()
    end function vegas_init
```

Finalize the grid. Deallocate grid memory.

⟨*vegas: vegas: TBP*⟩≡
```
    procedure, public :: final => vegas_final
```

⟨*vegas: procedures*⟩+≡
```
    subroutine vegas_final (self)
      class(vegas_t), intent(inout) :: self
      deallocate (self%grid%x_upper)
      deallocate (self%grid%x_lower)
      deallocate (self%grid%delta_x)
      deallocate (self%d)
      deallocate (self%grid%xi)
      deallocate (self%box)
      deallocate (self%bin)
    end subroutine vegas_final
```

20.7   Get-/Set-methods

The VEGAS object prohibits direct access from outside. Communication is
handle via get- or set-methods. Set the limits of integration. The defaults
limits correspong the n-dimensionl unit hypercube.

Remark: After setting the limits, the grid is initialised, again. Previous
results are lost due to recalculation of the overall jacobian.

⟨*vegas: vegas: TBP*⟩+≡
```
    procedure, public :: set_limits => vegas_set_limits
```

⟨*vegas: procedures*⟩+≡
```
    subroutine vegas_set_limits (self, x_lower, x_upper)
      class(vegas_t), intent(inout) :: self
```

```
      real(default), dimension(:), intent(in) :: x_lower

```

20.8   Grid resize- and refinement

Before integration the grid itself must be initialised. Given the number of
n_calls and **n_dim** we prepare the grid for the integration.

The grid is binned according to the VEGAS mode and **n_calls**. If the mode
is not set to **vegas_importance_only**, the grid is divided in to equal boxes. We
try for 2 calls per box

$$boxes = \sqrt[n_{dim}]{\frac{calls}{2}}.\tag{20.1}$$

If the numbers of boxes exceeds the number of bins, which is the case for low
dimensions, the algorithm switches to stratified sampling. Otherwise, we are
still using importance sampling, but keep the boxes for book keeping. If the
number of bins changes from the previous invocation, bins are expanded or
contracted accordingly, while preserving bin density.

⟨*vegas: vegas: TBP*⟩+≡
```
    procedure, private :: init_grid => vegas_init_grid
```

⟨*vegas: procedures*⟩+≡
```
    subroutine vegas_init_grid (self)
      class(vegas_t), intent(inout) :: self
      integer :: n_bins, n_boxes, box_per_bin, n_total_boxes
      real(default), dimension(:, :), allocatable :: w
      n_bins = self%config%n_bins_max
      n_boxes = 1
      if (self%config%mode /= VEGAS_MODE_IMPORTANCE_ONLY) then
         ! We try for 2 calls per box
         n_boxes = max (floor ((self%config%n_calls / 2.)**(1. / self%config%n_dim)), 1)
         self%config%mode = VEGAS_MODE_IMPORTANCE
         if (2 * n_boxes >= self%config%n_bins_max) then
            ! if n_bins/box < 2
            box_per_bin = max (n_boxes / self%config%n_bins_max, 1)
            n_bins =  min (n_boxes / box_per_bin, self%config%n_bins_max)
```

2681

```
         n_boxes = box_per_bin * n_bins
         self%config%mode = VEGAS_MODE_STRATIFIED
      end if
   end if
   n_total_boxes = n_boxes**self%config%n_dim
   self%config%calls_per_box = max (floor (real (self%config%n_calls) / n_total_boxes), 2)
   self%config%n_calls = self%config%calls_per_box * n_total_boxes
   !  Total volume of x-space/(average n_calls per bin)
   self%jacobian = self%hypercube_volume * real(n_bins, default)&
        &**self%config%n_dim / real(self%config%n_calls, default)
   self%config%n_boxes = n_boxes
   if (n_bins /= self%config%n_bins) then
      allocate (w(self%config%n_bins, self%config%n_dim), source=1.0_default)
      call self%grid%resize (n_bins, w)
      self%config%n_bins = n_bins
   end if
 end subroutine vegas_init_grid
```

Reset the cumulative result, and efficiency and max. grid values.

⟨*vegas: vegas: TBP*⟩+≡
```
   procedure, public :: reset_result => vegas_reset_result
```

⟨*vegas: procedures*⟩+≡
```
   subroutine vegas_reset_result (self)
     class(vegas_t), intent(inout) :: self
     self%result%sum_int_wgtd = 0.
     self%result%sum_wgts = 0.
     self%result%sum_chi = 0.
     self%result%it_num = 0
     self%result%samples = 0
     self%result%chi2 = 0
     self%result%efficiency = 0.
     self%result%efficiency_pos = 0.
     self%result%efficiency_neg = 0.
     self%result%max_abs_f = 0.
     self%result%max_abs_f_pos = 0.
     self%result%max_abs_f_neg = 0.
   end subroutine vegas_reset_result
```

Reset the grid. Purge the adapted grid and the distribution. Furthermore, reset
the results. The maximal size of the grid remains.
   Note: Handle **vegas_reset_grid** with great care! Instead of reusing an old
object, create a new one.

⟨*vegas: vegas: TBP*⟩+≡
```
   procedure, public :: reset_grid => vegas_reset_grid
```

⟨*vegas: procedures*⟩+≡
```
   subroutine vegas_reset_grid (self)
     class(vegas_t), intent(inout) :: self
     self%config%n_bins = 1
     self%d = 0._default
     self%grid%xi = 0._default
     self%grid%xi(1, :) = 0._default
     self%grid%xi(2, :) = 1._default
```

```
        call self%reset_result ()
    end subroutine vegas_reset_grid
```

Refine the grid to match the distribution `d`.

Average the distribution over neighbouring bins, then contract or expand the bins. The averaging dampens high fluctuations amog the integrand or the variance.

We make the type-bound procedure public accessible because the multi-channel integration refines each grid after integration over all grids.

⟨*vegas: vegas: TBP*⟩+≡

```
    procedure, public :: refine => vegas_refine_grid
```

⟨*vegas: procedures*⟩+≡

```
    subroutine vegas_refine_grid (self)
      class(vegas_t), intent(inout) :: self
      integer :: j
      real(default), dimension(self%config%n_bins, self%config%n_dim) :: w
      ndim: do j = 1, self%config%n_dim
         call average_distribution (self%config%n_bins, self%d(:self%config&
              &%n_bins, j), self%config%alpha, w(:, j))
      end do ndim
      call self%grid%resize (self%config%n_bins, w)
    contains
      ⟨vegas: vegas refine grid: procedures⟩
    end subroutine vegas_refine_grid
```

We average the collected values `d` of the (sq.) weighted `f` over neighbouring bins. The averaged `d` are then agian damped by a logarithm to enhance numerical stability. The results are then the refinement weights `w`.

We have to take care of the special case where we have a very low sampling rate. In those cases we can not be sure that the distribution is satisfying filled, although we have already averaged over neighbouring bins. This will lead to a squashing of the unfilled bins and such the boundaries of those will be pushed together. We circumvent this problem by setting those unfilled bins to the smallest representable value of a default real.

The problem becomes very annoying in the multi-channel formualae where have to look up via binary search the corresponding probability of `x` and if the width is zero, the point will be neglected.

⟨*vegas: vegas refine grid: procedures*⟩≡

```
    subroutine average_distribution (n_bins, d, alpha, w)
      integer, intent(in) :: n_bins
      real(default), dimension(:), intent(inout) :: d

20.9 Integration

Integrate `func`, in the previous set bounds `x_lower` to `x_upper`, with `n_calls`. Use results from previous invocations of `integrate` with `opt_reset_result = .false.` and better with subsequent calls.

Before we walk through the hybercube, we initialise the grid (at a central position).

We step through the (equidistant) boxes which ensure we do not miss any place in the n-dim. hypercube. In each box we sample `calls_per_box` random points and transform them to bin coordinates. The total integral and the total (sample) variance over each box i is then calculated by

$$E(I)_i = \sum_j^{\text{calls per box}} I_{i,j},$$

$$V(I)_i = \text{calls per box} \frac{\sum_j^{\text{calls per box}} I^2}{I}_{i,j} - (\sum_j^{\text{calls per box}} I_{i,j}) ** 2 \frac{\text{calls per box}}{\text{calls per box} - 1}.$$

The stratification of the n-dimensional hybercube allows a simple parallelisation of the algorithm (R. Kreckel, "Parallelization of adaptive MC integrators", Computer Physics Communications, vol. 106, no. 3, pp. 258266, Nov. 1997.). We have to ensure that all boxes are sampled, but the number of boxes to distribute is too large. We allow each thread to sample a fraction r of all boxes k such that $r \ll k$. Furthermore, we constrain that the number of process p is much smaller than r.

The overall constraint is

$$p \ll r \ll k. \tag{20.2}$$

We divide the intgeration into a parallel and a perpendicular subspace. The number of parallel dimensions is $D_{\parallel} = \lfloor \frac{D}{2} \rfloor$.

  do j = size (box), 1, -1
     box(j) = box(j) + 1
     if (box(j) <= self%config%n_boxes) return
     box(j) = 1
  end do
  success = .false.
end subroutine increment_box_coord
```

We parallelize `VEGAS` in simple forward manner. The hyper-cube is dissambled in to equidistant boxes in which we sample the integrand `calls_per_box` times. The workload of calculating those boxes is distributed along the worker.

The number of dimensions which will be parallelised are $\lfloor \frac{D}{2} \rfloor$, such MPI Variables for `vegas_integrate`. We have to duplicate all buffers for `MPI_Ireduce`,

because we cannot use the same send or receive buffer.

We temporarily store a (empty) grid, before communicating.

⟨*MPI: vegas: vegas integrate: variables*⟩≡
```
integer :: rank
type(vegas_grid_t) :: grid
```

MPI procedure-specific initialization.

⟨*MPI: vegas: vegas integrate: initialization*⟩≡
```
call MPI_Comm_size (MPI_COMM_WORLD, n_size)
call MPI_Comm_rank (MPI_COMM_WORLD, rank)
```

Pre-sampling communication.

We make a copy of the (actual) grid, which is unfilled when non-root. The actual grid is then broadcasted among the workers and inserted into the VEGAS object.

⟨*MPI: vegas: vegas integrate: pre sampling*⟩≡
```
if (self%is_parallelizable ()) then
   grid = self%get_grid ()
   call grid%broadcast ()
   call self%set_grid (grid)
end if
```

Start index of the boxes for different ranks. If the random number generator is RngStream, we can advance the current stream in such a way, that we will getting matching numbers. Iff **n_boxes** is larger than 2, otherwise parallelization is useless.

⟨*MPI: vegas: vegas integrate: pre sampling*⟩+≡
```
if (self%is_parallelizable ()) then
   do k = 1, rank
      call increment_box_coord (self%box(1:n_dim_par), box_success)
      if (.not. box_success) exit
   end do
   select type (rng)
   type is (rng_stream_t)
      call rng%advance_state (self%config%n_dim * self%config%calls_per_box&
           & * self%config%n_boxes**(self%config%n_dim - n_dim_par) * rank)
   end select
end if
```

Increment **n_size** times the box coordinates.

⟨*MPI: vegas: vegas integrate: sampling*⟩≡
```
if (self%is_parallelizable ()) then
   select type (rng)
   type is (rng_stream_t)
      call rng%advance_state (self%config%n_dim * self%config%calls_per_box&
           & * self%config%n_boxes**(self%config%n_dim - n_dim_par) * (n_size - 1))
   end select
end if
```

Call to **vegas_integrate_collect**.

⟨*MPI: vegas: vegas integrate: post sampling*⟩≡
```
if (self%is_parallelizable ()) then
   call vegas_integrate_collect ()

           & * func%evaluate (x)
    end subroutine vegas_generate_weighted_event
```

Generate random event. We accept on the rate

$$\frac{|f(x)|}{\max_x |f(x)|}. \tag{20.5}$$

We keep separate maximum weights for positive and negative weights, and use them, accordingly. In the case of unweighted event generation, if the current weight exceeds the the maximum weight, we update the maximum, accordingly.

```

Test function

We use the example from the Monte Carlo Examples of the GSL library

$$I = \int_{-pi}^{+pi} dk_x/(2pi) \int_{-pi}^{+pi} dk_y/(2pi) \int_{-pi}^{+pi} dk_z/(2pi) 1/(1 - cos(k_x)cos(k_y)cos(k_z)).$$

(20.6)

The integral is reduced to region $(0,0,0) \rightarrow (\pi, \pi, \pi)$ and multiplied by 8.

⟨*vegas: test types*⟩≡
```
type, extends (vegas_func_t) :: vegas_test_func_t
   !
 contains
 ⟨vegas: vegas test func: TBP⟩
end type vegas_test_func_t
```

Evaluate the integrand.

⟨*vegas: vegas test func: TBP*⟩≡
```
procedure, public :: evaluate => vegas_test_func_evaluate
```

⟨*vegas: tests*⟩≡
```
real(default) function vegas_test_func_evaluate (self, x) result (f)
  class(vegas_test_func_t), intent(inout) :: self
  real(default), dimension(:), intent(in) :: x
  f = 1.0 / (pi**3)
  f = f / ( 1.0 - cos (x(1)) * cos (x(2)) * cos (x(3)))
end function vegas_test_func_evaluate
```

The second test function is the normalised n-dim. gaussian distribution.

⟨*vegas: test types*⟩+≡
```
type, extends (vegas_func_t) :: vegas_gaussian_test_func_t
   !
 contains
 ⟨vegas: vegas gaussian test func: TBP⟩
end type vegas_gaussian_test_func_t
```

Evaluate the integrand.

⟨*vegas: vegas gaussian test func: TBP*⟩≡
```
procedure, public :: evaluate => vegas_gaussian_evaluate
```

⟨*vegas: tests*⟩+≡
```
real(default) function vegas_gaussian_evaluate (self, x) result (f)
  class(vegas_gaussian_test_func_t), intent(inout) :: self
  real(default), dimension(:), intent(in) :: x
  real(default), parameter :: inv_sqrt_pi = 1._default / sqrt(pi)
  f = inv_sqrt_pi**size (x)
  f = f * exp (- dot_product(x, x))
end function vegas_gaussian_evaluate
```

The third test function is a three-dimensional polynomial function which factories. The function is defined in such a way that the integral in the unit range is normalised to zero.

$$f(x) = -\frac{8}{3}(x+1) * (y-1) * z \qquad (20.7)$$

⟨*vegas: test types*⟩+≡
```

20.12.1   Type: vamp2_func_t

We extend `vegas_func_t` with the multi-channel weights and the `vegas_grid_t`, such that, the overall multi-channel weight can be calculated by the function itself.

We add an additional logicial `valid_x`, if it is set to `.false.`, we do not compute weighted function and just set the weighted integrand to zero. This behavior is in particular very useful, if a mapping is prohibited or fails. Or in the case of WHIZARD, a phase cut is applied.

Set n_chains and the (actual) chains. chain must have size n_channels and
each elements must store an index to a corresponding chain. This means, that
channels with equal index correspond to the same chain, and we refer to those
as chained weights, where we average the contributions of the chained weights
in vamp2_adapt_weights.

```

Adapt. We adapt the weights due the contribution of variances with $\beta > 0$.

$$\alpha_i = \frac{\alpha_i V_i^{\beta}}{\sum_i \alpha_i V_i^{\beta}} \qquad (20.9)$$

If `n_calls_threshold` is set, we rescale the weights in such a way, that the `n_calls` for each channel are greater than `n_calls_threshold`. We calculate the distance of the weights to the `weight_min` and reset those weights which are less than `weight_mins` to this value. The other values are accordingly resized to fit the boundary condition of the partition of unity.

      self%result%chi2 = 0
      self%result%efficiency = 0.
    end subroutine vamp2_reset_result
```

Integrate. We integrate each channel separately and combine the results

$$I = \sum_i \alpha_i I_i, \tag{20.10}$$

$$\sigma^2 = \sum_i \alpha_i^2 \sigma_i^2. \tag{20.11}$$

2726

Although, the (population) variance is given by

$$\sigma^2 = \frac{1}{N} \left(\sum_i \alpha_i I_i^2 - I^2 \right)$$

$$= \frac{1}{N-1} \left(\sum_i \left(N_i \sigma_i^2 + I_i^2 \right) - I^2 \right) \qquad (20.12)$$

$$= \frac{1}{N-1} \left(\sum_i \alpha_i \sigma_i^2 + \alpha_i I_i^2 - I^2 \right),$$

where we used $\sigma_i^2 = \frac{1}{N} \left(\langle I_i^2 \rangle - \langle I_i \rangle^2 \right)$, we use the approximation for numeric stability. The population variance relates to sample variance

$$s^2 = \frac{n}{n-1} \sigma^2, \qquad (20.13)$$

which gives an unbiased error estimate.

Beside those adaption to multichannel, the overall processing of `total_integral`, `total_sq_integral` and `total_variance` is the same as in `vegas_integrate`.

   ⟨vamp2: vamp2 generate event: procedures⟩
   end subroutine vamp2_generate_unweighted_event
```

Prepare event generation. We have to set the channel weights and the grids for the integrand's object.

We use an ansatz proposed by T. Ohl in the original VAMP code where we do not have to accept on

$$\frac{w_i(x)}{\max_{i,x} w_i(x)},$$

after we have selected a channel by the weights α_i. But rather, we use a more efficient way where we rescale the channel weights α_i

$$\alpha_i \to \alpha_i \frac{\max_x w_i(x)}{\max_{i,x} w_i(x)}.$$

The overall magic is to insert a "1" and to move the uneasy part into the channel selection, such that we can generate events likewise in the single channel mode. We generate an unweighted event by

$$\frac{w_i(x)}{\max_x w_i x},$$

after we have selected a channel by the rescaled event channel weights. The overall normalization $\max_{i,x}$ is not needed because we normalize the event channel weights to one and therefore the overall normalization cancels.

⟨vamp2: vamp2 generate event: procedures⟩≡
```
   subroutine prepare_event ()
     integer :: i
     self%event_prepared = .false.
     do i = 1, self%config%n_channel
        func%wi(i) = self%weight(i)
        func%grids(i) = self%integrator(i)%get_grid ()
     end do
     if (any (self%integrator%get_max_abs_f () > 0)) then
        self%event_weight = self%weight * self%integrator%get_max_abs_f ()
     else
        self%event_weight = self%weight
     end if
     self%event_weight = self%event_weight / sum (self%event_weight)
     self%event_prepared = .true.
   end subroutine prepare_event

Test function

We use the example from the Monte Carlo Examples of the GSL library

$$I = \int_{-pi}^{+pi} dk_x/(2pi) \int_{-pi}^{+pi} dk_y/(2pi) \int_{-pi}^{+pi} dk_z/(2pi) 1/(1-cos(k_x)cos(k_y)cos(k_z)).$$
(20.14)

The integral is reduced to region $(0,0,0) \to (\pi, \pi, \pi)$ and multiplied by 8.

⟨vamp2: test types⟩≡

Chapter 21

Multi-Channel Integration

The abstract representation of multi-channel Monte Carlo algorithms for integration and event generation.

Module `mci_base`: The abstract types and their methods. It provides a test integrator that is referenced in later unit tests.

iterations Container for defining integration call and pass settings.

integration_results This module handles results from integrating processes. It records passes and iterations, calculates statistical averages, and provides the user output of integration results.

These are the implementations:

Module `mci_midpoint`: A simple integrator that uses the midpoint rule to sample the integrand uniformly over the unit hypercube. There is only one integration channel, so this can be matched only to single-channel phase space.

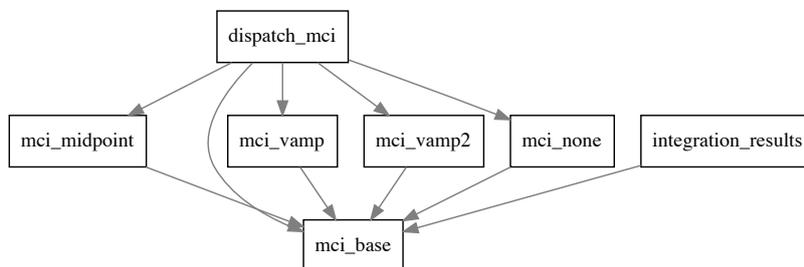
Module `mci_vamp`: Interface for the VAMP package.


Figure 21.1: Module dependencies in `src/mci`.

21.1 Generic Integrator

This module provides a multi-channel integrator (MCI) base type, a corresponding configuration type, and methods for integration and event generation.

⟨`mci_base.f90`⟩≡

  ⟨*MCI base: interfaces*⟩

    contains

  ⟨*MCI base: procedures*⟩

  end module mci_base

21.1.1 MCI: integrator

The MCI object contains the methods for integration and event generation. For the actual work and data storage, it spawns an MCI instance object.

The base object contains the number of integration dimensions and the number of channels as configuration data. Further configuration data are stored in the concrete extensions.

The MCI sum contains all relevant information about the integrand. It can be used for comparing the current configuration against a previous one. If they match, we can skip an actual integration. (Implemented only for the VAMP version.)

There is a random-number generator (its state with associated methods) available as `rng`. It may or may not be used for integration. It will be used for event generation.

⟨*MCI base: public*⟩≡

              mci%n_dim, "dimensions"
      end if
      call msg_message (unit = unit)
    end subroutine mci_startup_message
```

Dump type-specific info to a logfile.

⟨MCI base: mci: TBP⟩+≡
```
    procedure(mci_write_log_entry), deferred :: write_log_entry
```

⟨MCI base: interfaces⟩≡
```
    abstract interface
```

```
      subroutine mci_write_log_entry (mci, u)
        import
        class(mci_t), intent(in) :: mci
        integer, intent(in) :: u
      end subroutine mci_write_log_entry
    end interface
```

In order to avoid dependencies on definite MCI implementations, we introduce a MD5 sum calculator.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure(mci_compute_md5sum), deferred :: compute_md5sum
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
      subroutine mci_compute_md5sum (mci, pacify)
        import
        class(mci_t), intent(inout) :: mci
        logical, intent(in), optional :: pacify
      end subroutine mci_compute_md5sum
    end interface
```

Record the index of the MCI object within a process. For multi-component processes with more than one integrator, the integrator should know about its own index, so file names can be unique, etc. The default implementation does nothing, however.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: record_index => mci_record_index
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_record_index (mci, i_mci)
      class(mci_t), intent(inout) :: mci
      integer, intent(in) :: i_mci
    end subroutine mci_record_index
```

There is no Initializer for the abstract type, but a generic setter for the number of channels and dimensions. We make two aliases available, to be able to override it.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: set_dimensions => mci_set_dimensions
    procedure :: base_set_dimensions => mci_set_dimensions
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_set_dimensions (mci, n_dim, n_channel)
      class(mci_t), intent(inout) :: mci
      integer, intent(in) :: n_dim
      integer, intent(in) :: n_channel
      mci%n_dim = n_dim
      mci%n_channel = n_channel
    end subroutine mci_set_dimensions
```

Declare particular dimensions as flat. This information can be used to simplify integration. When generating events, the flat dimensions should be sampled with uniform and uncorrelated distribution. It depends on the integrator what to do with that information.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure (mci_declare_flat_dimensions), deferred :: declare_flat_dimensions
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
       subroutine mci_declare_flat_dimensions (mci, dim_flat)
         import
         class(mci_t), intent(inout) :: mci
         integer, dimension(:), intent(in) :: dim_flat
       end subroutine mci_declare_flat_dimensions
    end interface
```

Declare particular channels as equivalent, possibly allowing for permutations or reflections of dimensions. We use the information stored in the **phs_channel_t** object array that the phase-space module provides.

(We do not test this here, deferring the unit test to the **mci_vamp** implementation where we actually use this feature.)

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure (mci_declare_equivalences), deferred :: declare_equivalences
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
       subroutine mci_declare_equivalences (mci, channel, dim_offset)
         import
         class(mci_t), intent(inout) :: mci
         type(phs_channel_t), dimension(:), intent(in) :: channel
         integer, intent(in) :: dim_offset
       end subroutine mci_declare_equivalences
    end interface
```

Declare particular channels as chained together. The implementation may use this array for keeping their weights equal to each other, etc.

The chain array is an array sized by the number of channels. For each channel, there is an integer entry that indicates the correponding chains. The total number of chains is the maximum value of this entry.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: declare_chains => mci_declare_chains
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_declare_chains (mci, chain)
      class(mci_t), intent(inout) :: mci
      integer, dimension(:), intent(in) :: chain
      allocate (mci%chain (size (chain)))
      mci%n_chain = maxval (chain)
      allocate (mci%chain_weights (mci%n_chain), source = 0._default)
      mci%chain = chain
    end subroutine mci_declare_chains
```

Collect channel weights according to chains and store them in the `chain_weights` for output. We sum up the weights for all channels that share the same `chain` index and store the results in the `chain_weights` array.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: collect_chain_weights => mci_collect_chain_weights
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_collect_chain_weights (mci, weight)
      class(mci_t), intent(inout) :: mci
      real(default), dimension(:), intent(in) :: weight
      integer :: i, c
      if (allocated (mci%chain)) then
        mci%chain_weights = 0
        do i = 1, size (mci%chain)
          c = mci%chain(i)
          mci%chain_weights(c) = mci%chain_weights(c) + weight(i)
        end do
      end if
    end subroutine mci_collect_chain_weights
```

Check if there are chains.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: has_chains => mci_has_chains
```

⟨*MCI base: procedures*⟩+≡
```
    function mci_has_chains (mci) result (flag)
      class(mci_t), intent(in) :: mci
      logical :: flag
      flag = allocated (mci%chain)
    end function mci_has_chains
```

Output of the chain weights, kept separate from the main `write` method.
   [The formatting will work as long as the number of chains is less than 10^{10}...]

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: write_chain_weights => mci_write_chain_weights
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_write_chain_weights (mci, unit)
      class(mci_t), intent(in) :: mci
      integer, intent(in), optional :: unit
      integer :: u, i, n, n_digits
      character(4) :: ifmt
      u = given_output_unit (unit)
      if (allocated (mci%chain_weights)) then
        write (u, "(1x,A)")  "Weights of channel chains (groves):"
        n_digits = 0
        n = size (mci%chain_weights)
        do while (n > 0)
          n = n / 10
          n_digits = n_digits + 1
        end do
        write (ifmt, "(A1,I1)") "I", n_digits
        do i = 1, size (mci%chain_weights)
          write (u, "(3x," // ifmt // ",F13.10)")  i, mci%chain_weights(i)
```

2755

```
      end do
    end if
  end subroutine mci_write_chain_weights
```

Set the MD5 sum, independent of initialization.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: set_md5sum => mci_set_md5sum
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_set_md5sum (mci, md5sum)
      class(mci_t), intent(inout) :: mci
      character(32), intent(in) :: md5sum
      mci%md5sum = md5sum
    end subroutine mci_set_md5sum
```

Initialize a new integration pass. This is not necessarily meaningful, so we provide an empty base method. The `mci_vamp` implementation overrides this.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: add_pass => mci_add_pass
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_add_pass (mci, adapt_grids, adapt_weights, final_pass)
      class(mci_t), intent(inout) :: mci
      logical, intent(in), optional :: adapt_grids
      logical, intent(in), optional :: adapt_weights
      logical, intent(in), optional :: final_pass
    end subroutine mci_add_pass
```

Allocate an instance with matching type. This must be deferred.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure (mci_allocate_instance), deferred :: allocate_instance
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
      subroutine mci_allocate_instance (mci, mci_instance)
        import
        class(mci_t), intent(in) :: mci
        class(mci_instance_t), intent(out), pointer :: mci_instance
      end subroutine mci_allocate_instance
    end interface
```

Import a random-number generator. We transfer the allocation of an existing generator state into the object. The generator state may already be initialized, or we can reset it by its `init` method.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: import_rng => mci_import_rng
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_import_rng (mci, rng)
      class(mci_t), intent(inout) :: mci
      class(rng_t), intent(inout), allocatable :: rng
      call move_alloc (rng, mci%rng)
    end subroutine mci_import_rng
```

Activate or deactivate the timer.

⟨MCI base: mci: TBP⟩+≡

```
    procedure :: set_timer => mci_set_timer
```

⟨MCI base: procedures⟩+≡

```
    subroutine mci_set_timer (mci, active)
      class(mci_t), intent(inout) :: mci
      logical, intent(in) :: active
      mci%use_timer = active
    end subroutine mci_set_timer
```

Start and stop signal for the timer, if active. The elapsed time can then be retrieved from the MCI record.

⟨MCI base: mci: TBP⟩+≡

```
    procedure :: start_timer => mci_start_timer
    procedure :: stop_timer => mci_stop_timer
```

⟨MCI base: procedures⟩+≡

```
    subroutine mci_start_timer (mci)
      class(mci_t), intent(inout) :: mci
      if (mci%use_timer)  call mci%timer%start ()
    end subroutine mci_start_timer

    subroutine mci_stop_timer (mci)
      class(mci_t), intent(inout) :: mci
      if (mci%use_timer)  call mci%timer%stop ()
    end subroutine mci_stop_timer
```

Sampler test. Evaluate the sampler a given number of times. Results are discarded, so we don't need the MCI instance which would record them.

The evaluation channel is iterated, and the x parameters are randomly chosen.

⟨MCI base: mci: TBP⟩+≡

```
    procedure :: sampler_test => mci_sampler_test
```

⟨MCI base: procedures⟩+≡

```
    subroutine mci_sampler_test (mci, sampler, n_calls)
      class(mci_t), intent(inout) :: mci
      class(mci_sampler_t), intent(inout), target :: sampler
      integer, intent(in) :: n_calls
      real(default), dimension(:), allocatable :: x_in, f
      real(default), dimension(:,:), allocatable :: x_out
      real(default) :: val
      integer :: i, c
      allocate (x_in (mci%n_dim))
      allocate (f (mci%n_channel))
      allocate (x_out (mci%n_dim, mci%n_channel))
      do i = 1, n_calls
         c = mod (i, mci%n_channel) + 1
         call mci%rng%generate_array (x_in)
         call sampler%evaluate (c, x_in, val, x_out, f)
      end do
    end subroutine mci_sampler_test
```

Integrate: this depends on the implementation. We foresee a pacify flag to take care of small numerical noise on different platforms.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure (mci_integrate), deferred :: integrate
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
       subroutine mci_integrate (mci, instance, sampler, &
            n_it, n_calls, results, pacify)
         import
         class(mci_t), intent(inout) :: mci
         class(mci_instance_t), intent(inout), target :: instance
         class(mci_sampler_t), intent(inout), target :: sampler
         integer, intent(in) :: n_it
         integer, intent(in) :: n_calls
         logical, intent(in), optional :: pacify
         class(mci_results_t), intent(inout), optional :: results
       end subroutine mci_integrate
    end interface
```

Event generation. Depending on the implementation, event generation may or may not require a previous integration pass.

Instead of a black-box `simulate` method, we require an initializer, a finalizer, and procedures for generating a single event. This allows us to interface simulation event by event from the outside, and it facilitates the further processing of an event after successful generation. For integration, this is not necessary.

The initializer has `intent(inout)` for the `mci` passed object. The reason is that the initializer can read integration results and grids from file, where the results can modify the `mci` record.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure (mci_prepare_simulation), deferred :: prepare_simulation
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
       subroutine mci_prepare_simulation (mci)
         import
         class(mci_t), intent(inout) :: mci
       end subroutine mci_prepare_simulation
    end interface
```

The generated event will reside in in the `instance` object (overall results and weight) and in the `sampler` object (detailed data). In the real application, we can subsequently call methods of the `sampler` in order to further process the generated event.

The `target` attributes are required by the VAMP implementation, which uses pointers to refer to the instance and sampler objects from within the integration function.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure (mci_generate), deferred :: generate_weighted_event
    procedure (mci_generate), deferred :: generate_unweighted_event
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
      subroutine mci_generate (mci, instance, sampler)
        import
        class(mci_t), intent(inout) :: mci
        class(mci_instance_t), intent(inout), target :: instance
        class(mci_sampler_t), intent(inout), target :: sampler
      end subroutine mci_generate
    end interface
```

This is analogous, but we rebuild the event from the information stored in `state` instead of generating it.

Note: currently unused outside of tests, might be deleted later.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure (mci_rebuild), deferred :: rebuild_event
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
      subroutine mci_rebuild (mci, instance, sampler, state)
        import
        class(mci_t), intent(inout) :: mci
        class(mci_instance_t), intent(inout) :: instance
        class(mci_sampler_t), intent(inout) :: sampler
        class(mci_state_t), intent(in) :: state
      end subroutine mci_rebuild
    end interface
```

Pacify: reduce numerical noise. The base implementation does nothing.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: pacify => mci_pacify
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_pacify (object, efficiency_reset, error_reset)
      class(mci_t), intent(inout) :: object
      logical, intent(in), optional :: efficiency_reset, error_reset
    end subroutine mci_pacify
```

Return the value of the integral, error, efficiency, and time per call.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: get_integral => mci_get_integral
    procedure :: get_error => mci_get_error
    procedure :: get_efficiency => mci_get_efficiency
    procedure :: get_time => mci_get_time
```

⟨*MCI base: procedures*⟩+≡
```
    function mci_get_integral (mci) result (integral)
      class(mci_t), intent(in) :: mci
      real(default) :: integral
      if (mci%integral_known) then
         integral = mci%integral
      else
         call msg_bug ("The integral is unknown. This is presumably a" // &
              "WHIZARD bug.")
```

```
      end if
    end function mci_get_integral

    function mci_get_error (mci) result (error)
      class(mci_t), intent(in) :: mci
      real(default) :: error
      if (mci%error_known) then
         error = mci%error
      else
         error = 0
      end if
    end function mci_get_error

    function mci_get_efficiency (mci) result (efficiency)
      class(mci_t), intent(in) :: mci
      real(default) :: efficiency
      if (mci%efficiency_known) then
         efficiency = mci%efficiency
      else
         efficiency = 0
      end if
    end function mci_get_efficiency

    function mci_get_time (mci) result (time)
      class(mci_t), intent(in) :: mci
      real(default) :: time
      if (mci%use_timer) then
         time = mci%timer
      else
         time = 0
      end if
    end function mci_get_time
```

Return the MD5 sum of the configuration. This may be overridden in an extension, to return a different MD5 sum.

⟨*MCI base: mci: TBP*⟩+≡
```
    procedure :: get_md5sum => mci_get_md5sum
```

⟨*MCI base: procedures*⟩+≡
```
    pure function mci_get_md5sum (mci) result (md5sum)
      class(mci_t), intent(in) :: mci
      character(32) :: md5sum
      md5sum = mci%md5sum
    end function mci_get_md5sum
```

21.1.2 MCI instance

The base type contains an array of channel weights. The value `mci_weight` is the combined MCI weight that corresponds to a particular sampling point.

For convenience, we also store the `x` and Jacobian values for this sampling point.

⟨*MCI base: public*⟩+≡

```
      public :: mci_instance_t
```

⟨*MCI base: types*⟩+≡
```
    type, abstract :: mci_instance_t
      logical :: valid = .false.
      real(default), dimension(:), allocatable :: w
      real(default), dimension(:), allocatable :: f
      real(default), dimension(:,:), allocatable :: x
      integer :: selected_channel = 0
      real(default) :: mci_weight = 0
      real(default) :: integrand  = 0
      logical :: negative_weights = .false.
      integer :: n_dropped = 0
     contains
     ⟨MCI base: mci instance: TBP⟩
    end type mci_instance_t
```

Output: deferred

⟨*MCI base: mci instance: TBP*⟩≡
```
    procedure (mci_instance_write), deferred :: write
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
      subroutine mci_instance_write (object, unit, pacify)
        import
        class(mci_instance_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: pacify
      end subroutine mci_instance_write
    end interface
```

A finalizer, just in case.

⟨*MCI base: mci instance: TBP*⟩+≡
```
    procedure (mci_instance_final), deferred :: final
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
      subroutine mci_instance_final (object)
        import
        class(mci_instance_t), intent(inout) :: object
      end subroutine mci_instance_final
    end interface
```

Init: basic initializer for the arrays, otherwise deferred. Assigning the `mci` object
is also deferred, because it depends on the concrete type.
    The weights are initialized with an uniform normalized value.

⟨*MCI base: mci instance: TBP*⟩+≡
```
    procedure (mci_instance_base_init), deferred :: init
    procedure :: base_init => mci_instance_base_init
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_instance_base_init (mci_instance, mci)
      class(mci_instance_t), intent(out) :: mci_instance
      class(mci_t), intent(in), target :: mci
```

```
      allocate (mci_instance%w (mci%n_channel))
      allocate (mci_instance%f (mci%n_channel))
      allocate (mci_instance%x (mci%n_dim, mci%n_channel))
      if (mci%n_channel > 0) then
         call mci_instance%set_channel_weights &
              (spread (1._default, dim=1, ncopies=mci%n_channel))
      end if
      mci_instance%f = 0
      mci_instance%x = 0
   end subroutine mci_instance_base_init
```

Explicitly set the array of channel weights.

⟨*MCI base: mci instance: TBP*⟩+≡
```
   procedure :: set_channel_weights => mci_instance_set_channel_weights
```

⟨*MCI base: procedures*⟩+≡
```
   subroutine mci_instance_set_channel_weights (mci_instance, weights, sum_non_zero)
     class(mci_instance_t), intent(inout) :: mci_instance
     real(default), dimension(:), intent(in) :: weights
     logical, intent(out), optional :: sum_non_zero
     real(default) :: wsum
     wsum = sum (weights)
     if (wsum /= 0) then
        mci_instance%w = weights / wsum
        if (present (sum_non_zero)) sum_non_zero = .true.
     else
        if (present (sum_non_zero)) sum_non_zero = .false.
        call msg_warning ("MC sampler initialization:&
              & sum of channel weights is zero")
     end if
   end subroutine mci_instance_set_channel_weights
```

Compute the overall weight factor for a configuration of x values and Jacobians f. The x values come in n_channel rows with n_dim entries each. The f factors constitute an array with n_channel entries.

We assume that the x and f arrays are already stored inside the MC instance. The result is also stored there.

⟨*MCI base: mci instance: TBP*⟩+≡
```
   procedure (mci_instance_compute_weight), deferred :: compute_weight
```

⟨*MCI base: interfaces*⟩+≡
```
   abstract interface
     subroutine mci_instance_compute_weight (mci, c)
       import
       class(mci_instance_t), intent(inout) :: mci
       integer, intent(in) :: c
     end subroutine mci_instance_compute_weight
   end interface
```

Record the integrand as returned by the sampler. Depending on the implementation, this may merely copy the value, or do more complicated things.

We may need the MCI weight for the actual computations, so this should be called after the previous routine.

⟨*MCI base: mci instance: TBP*⟩+≡
```
    procedure (mci_instance_record_integrand), deferred :: record_integrand
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
       subroutine mci_instance_record_integrand (mci, integrand)
         import
         class(mci_instance_t), intent(inout) :: mci
         real(default), intent(in) :: integrand
       end subroutine mci_instance_record_integrand
    end interface
```

Sample a point directly: evaluate the sampler, then compute the weight and the weighted integrand. Finally, record the integrand within the MCI instance.

If a signal (interrupt) was raised recently, we abort the calculation before entering the sampler. Thus, a previous calculation will have completed and any data are already recorded, but any new point can be discarded. If the abort flag is present, we may delay the interrupt, so we can do some cleanup.

⟨*MCI base: mci instance: TBP*⟩+≡
```
    procedure :: evaluate => mci_instance_evaluate
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_instance_evaluate (mci, sampler, c, x)
      class(mci_instance_t), intent(inout) :: mci
      class(mci_sampler_t), intent(inout) :: sampler
      integer, intent(in) :: c
      real(default), dimension(:), intent(in) :: x
      real(default) :: val
      call sampler%evaluate (c, x, val, mci%x, mci%f)
      mci%valid = sampler%is_valid ()
      if (mci%valid) then
         call mci%compute_weight (c)
         call mci%record_integrand (val)
      end if
    end subroutine mci_instance_evaluate
```

Initiate and terminate simulation. In contrast to integration, we implement these as methods of the process instance, since the mci configuration object is unchanged.

The safety factor reduces the acceptance probability for unweighted events. The implementation of this feature depends on the concrete type.

⟨*MCI base: mci instance: TBP*⟩+≡
```
    procedure (mci_instance_init_simulation), deferred :: init_simulation
    procedure (mci_instance_final_simulation), deferred :: final_simulation
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
       subroutine mci_instance_init_simulation (instance, safety_factor)
         import
         class(mci_instance_t), intent(inout) :: instance
         real(default), intent(in), optional :: safety_factor
```

```
      end subroutine mci_instance_init_simulation
   end interface

   abstract interface
      subroutine mci_instance_final_simulation (instance)
        import
        class(mci_instance_t), intent(inout) :: instance
      end subroutine mci_instance_final_simulation
   end interface
```

Assuming that the sampler is in a completely defined state, just extract the data that `evaluate` would compute. Also record the integrand.

⟨*MCI base: mci instance: TBP*⟩+≡
```
   procedure :: fetch => mci_instance_fetch
```

⟨*MCI base: procedures*⟩+≡
```
   subroutine mci_instance_fetch (mci, sampler, c)
     class(mci_instance_t), intent(inout) :: mci
     class(mci_sampler_t), intent(in) :: sampler
     integer, intent(in) :: c
     real(default) :: val
     mci%valid = sampler%is_valid ()
     if (mci%valid) then
        call sampler%fetch (val, mci%x, mci%f)
        call mci%compute_weight (c)
        call mci%record_integrand (val)
     end if
   end subroutine mci_instance_fetch
```

The value, i.e., the weighted integrand, is the integrand (which should be taken as-is from the sampler) multiplied by the MCI weight.

⟨*MCI base: mci instance: TBP*⟩+≡
```
   procedure :: get_value => mci_instance_get_value
```

⟨*MCI base: procedures*⟩+≡
```
   function mci_instance_get_value (mci) result (value)
     class(mci_instance_t), intent(in) :: mci
     real(default) :: value
     if (mci%valid) then
        value = mci%integrand * mci%mci_weight
     else
        value = 0
     end if
   end function mci_instance_get_value
```

This is an extra routine. By default, the event weight is equal to the value returned by the previous routine. However, if we select a channel for event generation not just based on the channel weights, the event weight has to account for this bias, so the event weight that applies to event generation is different. In that case, we should override the default routine.

⟨*MCI base: mci instance: TBP*⟩+≡
```
   procedure :: get_event_weight => mci_instance_get_value
```

Excess weight can occur during unweighted event generation, if the assumed maximum value of the integrand is too small. This excess should be normalized in the same way as the event weight above (which for unweighted events becomes unity).

⟨*MCI base: mci instance: TBP*⟩+≡
```
    procedure (mci_instance_get_event_excess), deferred :: get_event_excess
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
       function mci_instance_get_event_excess (mci) result (excess)
         import
         class(mci_instance_t), intent(in) :: mci
         real(default) :: excess
       end function mci_instance_get_event_excess
    end interface
```

Dropped events (i.e., events with zero weight that are not retained) are counted within the `mci_instance` object.

⟨*MCI base: mci instance: TBP*⟩+≡
```
    procedure :: get_n_event_dropped => mci_instance_get_n_event_dropped
    procedure :: reset_n_event_dropped => mci_instance_reset_n_event_dropped
    procedure :: record_event_dropped => mci_instance_record_event_dropped
```

⟨*MCI base: procedures*⟩+≡
```
    function mci_instance_get_n_event_dropped (mci) result (n_dropped)
      class(mci_instance_t), intent(in) :: mci
      integer :: n_dropped
      n_dropped = mci%n_dropped
    end function mci_instance_get_n_event_dropped

    subroutine mci_instance_reset_n_event_dropped (mci)
      class(mci_instance_t), intent(inout) :: mci
      mci%n_dropped = 0
    end subroutine mci_instance_reset_n_event_dropped

    subroutine mci_instance_record_event_dropped (mci)
      class(mci_instance_t), intent(inout) :: mci
      mci%n_dropped = mci%n_dropped + 1
    end subroutine mci_instance_record_event_dropped
```

21.1.3 MCI state

This object can hold the relevant information that allows us to reconstruct the MCI instance without re-evaluating the sampler completely.

We store the `x_in` MC input parameter set, which coincides with the section of the complete `x` array that belongs to a particular channel. We also store the MC function value. When we want to reconstruct the state, we can use the input array to recover the complete `x` and `f` arrays (i.e., the kinematics), but do not need to recompute the MC function value (the dynamics).

The `mci_state_t` may be extended, to allow storing/recalling more information. In that case, we would override the type-bound procedures. However, the

base type is also a concrete type and self-contained.

⟨*MCI base: public*⟩+≡
```
    public :: mci_state_t
```

⟨*MCI base: types*⟩+≡
```
    type :: mci_state_t
      integer :: selected_channel = 0
      real(default), dimension(:), allocatable :: x_in
      real(default) :: val
     contains
     ⟨MCI base: mci state: TBP⟩
    end type mci_state_t
```

Output:

⟨*MCI base: mci state: TBP*⟩≡
```
    procedure :: write => mci_state_write
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_state_write (object, unit)
      class(mci_state_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u
      u = given_output_unit (unit)
      write (u, "(1x,A)")  "MCI state:"
      write (u, "(3x,A,I0)")  "Channel   = ", object%selected_channel
      write (u, "(3x,A,999(1x,F12.10))")  "x (in)    =", object%x_in
      write (u, "(3x,A,ES19.12)")  "Integrand = ", object%val
    end subroutine mci_state_write
```

To store the object, we take the relevant section of the x array. The channel used for storing data is taken from the `instance` object, but it could be arbitrary in principle.

⟨*MCI base: mci instance: TBP*⟩+≡
```
    procedure :: store => mci_instance_store
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_instance_store (mci, state)
      class(mci_instance_t), intent(in) :: mci
      class(mci_state_t), intent(out) :: state
      state%selected_channel = mci%selected_channel
      allocate (state%x_in (size (mci%x, 1)))
      state%x_in = mci%x(:,mci%selected_channel)
      state%val = mci%integrand
    end subroutine mci_instance_store
```

Recalling the state, we must consult the sampler in order to fully reconstruct the x and f arrays. The integrand value is known, and we also give it to the sampler, bypassing evaluation.

The final steps are equivalent to the `evaluate` method above.

⟨*MCI base: mci instance: TBP*⟩+≡
```
    procedure :: recall => mci_instance_recall
```

⟨*MCI base: procedures*⟩+≡
```
    subroutine mci_instance_recall (mci, sampler, state)
      class(mci_instance_t), intent(inout) :: mci
      class(mci_sampler_t), intent(inout) :: sampler
      class(mci_state_t), intent(in) :: state
      if (size (state%x_in) == size (mci%x, 1) &
          .and. state%selected_channel <= size (mci%x, 2)) then
        call sampler%rebuild (state%selected_channel, &
             state%x_in, state%val, mci%x, mci%f)
        call mci%compute_weight (state%selected_channel)
        call mci%record_integrand (state%val)
      else
        call msg_fatal ("Recalling event: mismatch in channel or dimension")
      end if
    end subroutine mci_instance_recall
```

21.1.4   MCI sampler

A sampler is an object that implements a multi-channel parameterization of the unit hypercube. Specifically, it is able to compute, given a channel and a set of x MC parameter values, a the complete set of x values and associated Jacobian factors f for all channels.

Furthermore, the sampler should return a single real value, the integrand, for the given point in the hypercube.

It must implement a method `evaluate` for performing the above computations.

⟨*MCI base: public*⟩+≡
```
    public :: mci_sampler_t
```

⟨*MCI base: types*⟩+≡
```
    type, abstract :: mci_sampler_t
     contains
     ⟨MCI base: mci sampler: TBP⟩
    end type mci_sampler_t
```

Output, deferred to the implementation.

⟨*MCI base: mci sampler: TBP*⟩≡
```
    procedure (mci_sampler_write), deferred :: write
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
      subroutine mci_sampler_write (object, unit, testflag)
        import
        class(mci_sampler_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: testflag
      end subroutine mci_sampler_write
    end interface
```

The evaluation routine. Input is the channel index `c` and the one-dimensional parameter array `x_in`. Output are the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

⟨*MCI base: mci sampler: TBP*⟩+≡
```
procedure (mci_sampler_evaluate), deferred :: evaluate
```

⟨*MCI base: interfaces*⟩+≡
```
abstract interface
   subroutine mci_sampler_evaluate (sampler, c, x_in, val, x, f)
     import
     class(mci_sampler_t), intent(inout) :: sampler
     integer, intent(in) :: c
     real(default), dimension(:), intent(in) :: x_in
     real(default), intent(out) :: val
     real(default), dimension(:,:), intent(out) :: x
     real(default), dimension(:), intent(out) :: f
   end subroutine mci_sampler_evaluate
end interface
```

Query the validity of the sampling point. Can be called after `evaluate`.

⟨*MCI base: mci sampler: TBP*⟩+≡
```
procedure (mci_sampler_is_valid), deferred :: is_valid
```

⟨*MCI base: interfaces*⟩+≡
```
abstract interface
   function mci_sampler_is_valid (sampler) result (valid)
     import
     class(mci_sampler_t), intent(in) :: sampler
     logical :: valid
   end function mci_sampler_is_valid
end interface
```

The shortcut. Again, the channel index `c` and the parameter array `x_in` are input. However, we also provide the integrand value `val`, and we just require that the complete parameter array `x` and Jacobian array `f` are recovered.

⟨*MCI base: mci sampler: TBP*⟩+≡
```
procedure (mci_sampler_rebuild), deferred :: rebuild
```

⟨*MCI base: interfaces*⟩+≡
```
abstract interface
   subroutine mci_sampler_rebuild (sampler, c, x_in, val, x, f)
     import
     class(mci_sampler_t), intent(inout) :: sampler
     integer, intent(in) :: c
     real(default), dimension(:), intent(in) :: x_in
     real(default), intent(in) :: val
     real(default), dimension(:,:), intent(out) :: x
     real(default), dimension(:), intent(out) :: f
   end subroutine mci_sampler_rebuild
end interface
```

This routine should extract the important data from a sampler that has been filled by other means. We fetch the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

⟨*MCI base: mci sampler: TBP*⟩+≡
```
    procedure (mci_sampler_fetch), deferred :: fetch
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
       subroutine mci_sampler_fetch (sampler, val, x, f)
         import
         class(mci_sampler_t), intent(in) :: sampler
         real(default), intent(out) :: val
         real(default), dimension(:,:), intent(out) :: x
         real(default), dimension(:), intent(out) :: f
       end subroutine mci_sampler_fetch
    end interface
```

21.1.5 Results record

This is an abstract type which allows us to implement callback: each integration results can optionally be recorded to an instance of this object. The actual object may store a new result, average results, etc. It may also display a result on-line or otherwise, whenever the `record` method is called.

⟨*MCI base: public*⟩+≡
```
    public :: mci_results_t
```

⟨*MCI base: types*⟩+≡
```
    type, abstract :: mci_results_t
     contains
     ⟨MCI base: mci results: TBP⟩
    end type mci_results_t
```

The output routine is deferred. We provide an extra `verbose` flag, which could serve any purpose.

⟨*MCI base: mci results: TBP*⟩≡
```
    procedure (mci_results_write), deferred :: write
    procedure (mci_results_write_verbose), deferred :: write_verbose
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
       subroutine mci_results_write (object, unit, suppress)
         import
         class(mci_results_t), intent(in) :: object
         integer, intent(in), optional :: unit
         logical, intent(in), optional :: suppress
       end subroutine mci_results_write

       subroutine mci_results_write_verbose (object, unit)
         import
         class(mci_results_t), intent(in) :: object
         integer, intent(in), optional :: unit
       end subroutine mci_results_write_verbose
```

```
      end interface
```

This is the generic `record` method, which can be called directly from the integrator. The `record_extended` procedure store additionally the valid calls, positive and negative efficiency.

⟨*MCI base: mci results: TBP*⟩+≡
```
    generic :: record => record_simple, record_extended
    procedure (mci_results_record_simple), deferred :: record_simple
    procedure (mci_results_record_extended), deferred :: record_extended
```

⟨*MCI base: interfaces*⟩+≡
```
    abstract interface
      subroutine mci_results_record_simple (object, n_it, &
          n_calls, integral, error, efficiency, chain_weights, suppress)
        import
        class(mci_results_t), intent(inout) :: object
        integer, intent(in) :: n_it
        integer, intent(in) :: n_calls
        real(default), intent(in) :: integral
        real(default), intent(in) :: error
        real(default), intent(in) :: efficiency
        real(default), dimension(:), intent(in), optional :: chain_weights
        logical, intent(in), optional :: suppress
      end subroutine mci_results_record_simple

      subroutine mci_results_record_extended (object, n_it, n_calls,&
          & n_calls_valid, integral, error, efficiency, efficiency_pos,&
          & efficiency_neg, chain_weights, suppress)
        import
        class(mci_results_t), intent(inout) :: object
        integer, intent(in) :: n_it
        integer, intent(in) :: n_calls
        integer, intent(in) :: n_calls_valid
        real(default), intent(in) :: integral
        real(default), intent(in) :: error
        real(default), intent(in) :: efficiency
        real(default), intent(in) :: efficiency_pos
        real(default), intent(in) :: efficiency_neg
        real(default), dimension(:), intent(in), optional :: chain_weights
        logical, intent(in), optional :: suppress
      end subroutine mci_results_record_extended
    end interface
```

    end subroutine mci_base_test
```

2771

Test implementation of the configuration type

The concrete type contains the number of requested calls and the integral result, to be determined.

The `max_factor` entry is set for the actual test integration, where the integrand is not unity but some other constant value. This value should be set here, such that the actual maximum of the integrand is known when vetoing unweighted events.

    end subroutine mci_test_ignore_equivalences
```

Set the number of divisions to a nonzero value.

⟨*MCI base: tests*⟩+≡
```
    subroutine mci_test_set_divisions (object, divisions)
      class(mci_test_t), intent(inout) :: object
```

2773

```
      integer, intent(in) :: divisions
      object%divisions = divisions
    end subroutine mci_test_set_divisions
```

Set the maximum factor (default is 1).

⟨*MCI base: tests*⟩+≡

```
    subroutine mci_test_set_max_factor (object, max_factor)
      class(mci_test_t), intent(inout) :: object
      real(default), intent(in) :: max_factor
      object%max_factor = max_factor
    end subroutine mci_test_set_max_factor
```

Allocate instance with matching type.

⟨*MCI base: tests*⟩+≡

```
    subroutine mci_test_allocate_instance (mci, mci_instance)
      class(mci_test_t), intent(in) :: mci
      class(mci_instance_t), intent(out), pointer :: mci_instance
      allocate (mci_test_instance_t :: mci_instance)
    end subroutine mci_test_allocate_instance
```

Integrate: sample at the midpoints of uniform bits and add the results. We implement this for one and for two dimensions. In the latter case, we scan over two channels and multiply with the channel weights.

The arguments n_it and n_calls are ignored in this implementations.

The test integrator does not set error or efficiency, so those will remain undefined.

⟨*MCI base: tests*⟩+≡

```
    subroutine mci_test_integrate (mci, instance, sampler, &
        n_it, n_calls, results, pacify)

      class(mci_test_t), intent(inout) :: mci
    end subroutine mci_test_ignore_prepare_simulation
```

Event generator. We use mock random numbers for first selecting the channel
and then setting the x values. The results reside in the state of `instance` and
`sampler`.

⟨*MCI base: tests*⟩+≡

```
    subroutine mci_test_generate_weighted_event (mci, instance, sampler)
      class(mci_test_t), intent(inout) :: mci
      class(mci_instance_t), intent(inout), target :: instance
      class(mci_sampler_t), intent(inout), target :: sampler
      real(default) :: r
      real(default), dimension(:), allocatable :: x
      integer :: c
      select type (instance)
      type is (mci_test_instance_t)
         allocate (x (mci%n_dim))
         select case (mci%n_channel)
         case (1)
            c = 1
            call mci%rng%generate (x(1))
         case (2)
            call mci%rng%generate (r)
```

```
           if (r < instance%w(1)) then
              c = 1
           else
              c = 2
           end if
           call mci%rng%generate (x)
        end select
        call instance%evaluate (sampler, c, x)
     end select
   end subroutine mci_test_generate_weighted_event
```

For unweighted events, we generate weighted events and apply a simple rejection step to the relative event weight, until an event passes.

(This might result in an endless loop if we happen to be in sync with the mock random generator cycle. Therefore, limit the number of tries.)

⟨*MCI base: tests*⟩+≡
```
   subroutine mci_test_generate_unweighted_event (mci, instance, sampler)
     class(mci_test_t), intent(inout) :: mci
     class(mci_instance_t), intent(inout), target :: instance
     class(mci_sampler_t), intent(inout), target :: sampler
     real(default) :: r
     integer :: i
     select type (instance)
     type is (mci_test_instance_t)
        mci%tries = 0
        do i = 1, 10
           call mci%generate_weighted_event (instance, sampler)
           mci%tries = mci%tries + 1
           call mci%rng%generate (r)
           if (r < instance%rel_value)  exit
        end do
     end select
   end subroutine mci_test_generate_unweighted_event
```

Here, we rebuild the event from the state without consulting the rng.

⟨*MCI base: tests*⟩+≡
```
   subroutine mci_test_rebuild_event (mci, instance, sampler, state)

     class(mci_state_t), intent(in) :: state
     select type (instance)
     type is (mci_test_instance_t)
        call instance%recall (sampler, state)
     end select
   end subroutine mci_test_rebuild_event
```

Instance of the test MCI type

This instance type simulates the VAMP approach. We implement the VAMP multi-channel formula, but keep the channel-specific probability functions g_i

2776

smooth and fixed. We also keep the weights fixed.

The setup is as follows: we have n mappings of the unit hypercube

$$x = x(x^{(k)}) \qquad \text{where } x = (x_1, \ldots). \tag{21.1}$$

The Jacobian factors are the determinants

$$f^{(k)}(x^{(k)}) = \left| \frac{\partial x}{\partial x^{(k)}} \right| \tag{21.2}$$

We introduce arbitrary probability functions

$$g^{(k)}(x^{(k)}) \qquad \text{with} \quad \int dx^{(k)} g^{(k)}(x^{(k)}) = 1 \tag{21.3}$$

and weights

$$w_k \qquad \text{with} \quad \sum_k w_k = 1 \tag{21.4}$$

and construct the joint probability function

$$g(x) = \sum_k w_k \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \tag{21.5}$$

which also satisfies

$$\int g(x)\, dx = 1. \tag{21.6}$$

The algorithm implements a resolution of unity as follows

$$
\begin{aligned}
1 = \int dx &= \int \frac{g(x)}{g(x)} dx \\
&= \sum w_k \int \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \frac{dx}{g(x)} \\
&= \sum w_k \int g^{(k)}(x^{(k)}) \frac{dx^{(k)}}{g(x(x^{(k)}))}
\end{aligned}
\tag{21.7}
$$

where each of the integrals in the sum is evaluated using the channel-specific variables $x^{(k)}$.

We provide two examples: (1) trivial with one channel, one dimension, and all functions unity and (2) two channels and two dimensions with

$$
\begin{aligned}
x(x^{(1)}) &= (x_1^{(1)}, x_2^{(1)}) \\
x(x^{(2)}) &= (x_1^{(2)\,2}, x_2^{(2)})
\end{aligned}
\tag{21.8}
$$

hence

$$f^{(1)} \equiv 1, \qquad\qquad f^{(2)}(x^{(2)}) = 2x_1^{(2)} \tag{21.9}$$

The probability functions are

$$g^{(1)} \equiv 1, \qquad\qquad g^{(2)}(x^{(2)}) = 2x_2^{(2)} \tag{21.10}$$

In the concrete implementation of the integrator instance we store values for the channel probabilities g_i and the accumulated probability g.

We also store the result (product of integrand and MCI weight), the expected maximum for the result in each channel.

    end function mci_test_instance_get_event_excess
```

Test sampler

The test sampler implements a fixed configuration, either trivial (one-channel, one-dimension), or slightly nontrivial (two-channel, two-dimension). In the second channel, the first parameter is mapped according to $x_1 = x_1^{(2)2}$, so we have $f^{(2)}(x^{(2)}) = 2x_1^{(2)}$.

For display purposes, we store the return values inside the object. This is not strictly necessary.

⟨*MCI base: test types*⟩+≡

  call mci%final ()

  write (u, "(A)")
  write (u, "(A)")  "* Test output end: mci_base_3"

end subroutine mci_base_3
```

Event generation

We generate "random" events, one weighted and one unweighted. The test
implementation does not require an integration pass, we can generate events
immediately.

⟨*MCI base: execute tests*⟩+≡
```
    call test (mci_base_4, "mci_base_4", &
        "event generation (two channels)", &
        u, results)
```

⟨*MCI base: test declarations*⟩+≡
```
    public :: mci_base_4
```

⟨*MCI base: tests*⟩+≡
```
    subroutine mci_base_4 (u)
      integer, intent(in) :: u
      class(mci_t), allocatable, target :: mci
      class(mci_instance_t), pointer :: mci_instance => null ()
      class(mci_sampler_t), allocatable :: sampler
      class(rng_t), allocatable :: rng

      write (u, "(A)")  "* Test output: mci_base_4"
      write (u, "(A)")  "*   Purpose: generate events"
      write (u, "(A)")

      write (u, "(A)")  "* Initialize integrator, instance, sampler"
      write (u, "(A)")

      allocate (mci_test_t :: mci)
      call mci%set_dimensions (2, 2)
      select type (mci)
      type is (mci_test_t)
         call mci%set_divisions (10)
      end select

      call mci%allocate_instance (mci_instance)
      call mci_instance%init (mci)

      allocate (test_sampler_t :: sampler)
      select type (sampler)
      type is (test_sampler_t)
         call sampler%init (2)
      end select

      allocate (rng_test_t :: rng)
      call mci%import_rng (rng)

      write (u, "(A)")  "* Generate weighted event"
      write (u, "(A)")

      call mci%generate_weighted_event (mci_instance, sampler)

      call sampler%write (u)
      write (u, *)
      call mci_instance%write (u)
```

```
      write (u, "(A)")
      write (u, "(A)")  "* Generate unweighted event"
      write (u, "(A)")

      call mci%generate_unweighted_event (mci_instance, sampler)

      select type (mci)
      type is (mci_test_t)

      call mci_instance%write (u)

      call mci_instance%final ()
      call mci%final ()

      write (u, "(A)")
      write (u, "(A)")  "* Test output end: mci_base_4"

   end subroutine mci_base_4
```

Store and recall data

We generate an event and store the relevant data, i.e., the input parameters and
the result value for a particular channel. Then we use those data to recover the
event, as far as the MCI record is concerned.

⟨*MCI base: execute tests*⟩+≡
```
    call test (mci_base_5, "mci_base_5", &
         "store and recall", &
         u, results)
```

⟨*MCI base: test declarations*⟩+≡
```
    public :: mci_base_5
```

⟨*MCI base: tests*⟩+≡
```
    subroutine mci_base_5 (u)
      integer, intent(in) :: u
      class(mci_t), allocatable, target :: mci
      class(mci_instance_t), pointer :: mci_instance => null ()
      class(mci_sampler_t), allocatable :: sampler
      class(rng_t), allocatable :: rng
      class(mci_state_t), allocatable :: state

      write (u, "(A)")  "* Test output: mci_base_5"
      write (u, "(A)")  "*   Purpose: store and recall an event"
      write (u, "(A)")

      write (u, "(A)")  "* Initialize integrator, instance, sampler"
      write (u, "(A)")
```

21.2   Iterations

This module defines a container for the list of iterations and calls, to be submitted to integration.

⟨iterations.f90⟩≡
  ⟨*File header*⟩

  module iterations

  ⟨*Use kinds*⟩
  ⟨*Use strings*⟩
    use io_units
    use diagnostics

  ⟨*Standard module head*⟩

  ⟨*Iterations: public*⟩

  ⟨*Iterations: types*⟩

```
    contains

⟨Iterations: procedures⟩

    end module iterations
```

21.2.1 The iterations list

Each integration pass has a number of iterations and a number of calls per iteration. The last pass produces the end result; the previous passes are used for adaptation.

The flags `adapt_grid` and `adapt_weight` are used only if `custom_adaptation` is set. Otherwise, default settings are used that depend on the integration pass.

⟨*Iterations: types*⟩≡
```
    type :: iterations_spec_t
      private
      integer :: n_it = 0
      integer :: n_calls = 0
      logical :: custom_adaptation = .false.
      logical :: adapt_grids = .false.
      logical :: adapt_weights = .false.
    end type iterations_spec_t
```

We build up a list of iterations.

⟨*Iterations: public*⟩≡
```
    public :: iterations_list_t
```

⟨*Iterations: types*⟩+≡
```
    type :: iterations_list_t
      private
      integer :: n_pass = 0
      type(iterations_spec_t), dimension(:), allocatable :: pass
     contains
     ⟨Iterations: iterations list: TBP⟩
    end type iterations_list_t
```

Initialize an iterations list. For each pass, we have to specify the number of iterations and calls. We may provide the adaption conventions explicitly, either as character codes or as logicals.

For passes where the adaptation conventions are not specified, we use the following default setting: adapt weights and grids for all passes except the last one.

⟨*Iterations: iterations list: TBP*⟩≡
```
    procedure :: init => iterations_list_init
```

⟨*Iterations: procedures*⟩≡
```
    subroutine iterations_list_init &
        (it_list, n_it, n_calls, adapt, adapt_code, adapt_grids, adapt_weights)
      class(iterations_list_t), intent(inout) :: it_list
      integer, dimension(:), intent(in) :: n_it, n_calls
      logical, dimension(:), intent(in), optional :: adapt
```

```
      type(string_t), dimension(:), intent(in), optional :: adapt_code
      logical, dimension(:), intent(in), optional :: adapt_grids, adapt_weights
      integer :: i
      it_list%n_pass = size (n_it)
      if (allocated (it_list%pass)) deallocate (it_list%pass)
      allocate (it_list%pass (it_list%n_pass))
      it_list%pass%n_it = n_it
      it_list%pass%n_calls = n_calls
      if (present (adapt)) then
         it_list%pass%custom_adaptation = adapt
         do i = 1, it_list%n_pass
            if (adapt(i)) then
               if (verify (adapt_code(i), "wg") /= 0) then
                  call msg_error ("iteration specification: " &
                       // "adaptation code letters must be 'w' or 'g'")
               end if
               it_list%pass(i)%adapt_grids = scan (adapt_code(i), "g") /= 0
               it_list%pass(i)%adapt_weights = scan (adapt_code(i), "w") /= 0
            end if
         end do
      else if (present (adapt_grids) .and. present (adapt_weights)) then
         it_list%pass%custom_adaptation = .true.
         it_list%pass%adapt_grids = adapt_grids
         it_list%pass%adapt_weights = adapt_weights
      end if
      do i = 1, it_list%n_pass - 1
         if (.not. it_list%pass(i)%custom_adaptation) then
            it_list%pass(i)%adapt_grids = .true.
            it_list%pass(i)%adapt_weights = .true.
         end if
      end do
    end subroutine iterations_list_init
```

⟨*Iterations: iterations list: TBP*⟩+≡
```
    procedure :: clear => iterations_list_clear
```

⟨*Iterations: procedures*⟩+≡

    end subroutine iterations_2
```

21.3 Integration results

We record integration results and errors in a dedicated type. This allows us to do
further statistics such as weighted average, chi-squared, grouping by integration

passes, etc.

Note WHIZARD 2.2.0: This code is taken from the previous `processes` module essentially unchanged and converted into a separate module. It lacks an overhaul and, in particular, self-tests.

⟨`integration_results.f90`⟩≡
```
module integration_results

  ⟨Use kinds⟩
  ⟨Use strings⟩
    use io_units
    use format_utils, only: mp_format, pac_fmt
    use format_defs, only: FMT_10, FMT_14
    use diagnostics
    use md5
    use os_interface
    use mci_base

  ⟨Standard module head⟩

  ⟨Integration results: public⟩

  ⟨Integration results: parameters⟩

  ⟨Integration results: types⟩

  ⟨Integration results: interfaces⟩

  contains

  ⟨Integration results: procedures⟩

end module integration_results
```

21.3.1 Integration results entry

This object collects the results of an integration pass and makes them available to the outside.

The results object has to distinguish the process type:

We store the process type, the index of the integration pass and the absolute iteration index, the number of iterations contained in this result (for averages), and the integral (cross section or partial width), error estimate, efficiency.

For intermediate results, we set a flag if this result is an improvement w.r.t. previous ones.

The process type indicates decay or scattering. Dummy entries (skipped iterations) have a process type of `PRC_UNKNOWN`.

The additional information `n_calls_valid`, `efficiency_pos` and `efficiency_neg` are stored, but only used in verbose mode.

⟨Integration results: public⟩≡
```
    public :: integration_entry_t
```

⟨Integration results: types⟩≡
```
    type :: integration_entry_t
```

```
      private
      integer :: process_type = PRC_UNKNOWN
      integer :: pass = 0
      integer :: it = 0
      integer :: n_it = 0
      integer :: n_calls = 0
      integer :: n_calls_valid = 0
      logical :: improved = .false.
      real(default) :: integral = 0
      real(default) :: error = 0
      real(default) :: efficiency = 0
      real(default) :: efficiency_pos = 0
      real(default) :: efficiency_neg = 0
      real(default) :: chi2 = 0
      real(default), dimension(:), allocatable :: chain_weights
    contains
    ⟨Integration results: integration entry: TBP⟩
    end type integration_entry_t
```

The possible values of the type indicator:

⟨*Integration results: parameters*⟩≡
```
    integer, parameter, public :: PRC_UNKNOWN = 0
    integer, parameter, public :: PRC_DECAY = 1
    integer, parameter, public :: PRC_SCATTERING = 2
```

Initialize with all relevant data.

⟨*Integration results: interfaces*⟩≡
```
    interface integration_entry_t
       module procedure integration_entry_init
    end interface integration_entry_t
```

⟨*Integration results: procedures*⟩≡
```
    type(integration_entry_t) function integration_entry_init (process_type, pass,&

21.3.2 Combined integration results

We collect a list of results which grows during the execution of the program.
This is implemented as an array which grows if necessary; so we can easily
compute averages.

   We implement this as an extension of the `mci_results_t` which is defined
in `mci_base` as an abstract type. We thus decouple the implementation of the
integrator from the implementation of the results display, but nevertheless can
record intermediate results during integration. This implies that the present
extension implements a `record` method.

⟨*Integration results: public*⟩+≡
```
      public :: integration_results_t
```

2809

⟨*Integration results: types*⟩+≡
```
type, extends (mci_results_t) :: integration_results_t
  private
  integer :: process_type = PRC_UNKNOWN
  integer :: current_pass = 0
  integer :: n_pass = 0
  integer :: n_it = 0
  logical :: screen = .false.
  integer :: unit = 0
  integer :: verbosity = 0
  real(default) :: error_threshold = 0
  type(integration_entry_t), dimension(:), allocatable :: entry
  type(integration_entry_t), dimension(:), allocatable :: average
 contains
 ⟨Integration results: integration results: TBP⟩
end type integration_results_t
```

The array is extended in chunks of 10 entries.
⟨*Integration results: parameters*⟩+≡
```
integer, parameter :: RESULTS_CHUNK_SIZE = 10
```

The standard does not require to explicitly initialize the integers; however, some
gfortran version has a bug here and misses the default initialization in the type
definition.
⟨*Integration results: integration results: TBP*⟩≡
```
procedure :: init => integration_results_init
```
⟨*Integration results: procedures*⟩+≡
```
subroutine integration_results_init (results, process_type)
  class(integration_results_t), intent(out) :: results
  integer, intent(in) :: process_type
  results%process_type = process_type
  results%n_pass = 0
  results%n_it = 0
  allocate (results%entry (RESULTS_CHUNK_SIZE))
  allocate (results%average (RESULTS_CHUNK_SIZE))
end subroutine integration_results_init
```

Set verbose output of the integration results. In verbose mode, valid calls,
negative as positive efficiency will be printed.
⟨*Integration results: integration results: TBP*⟩+≡
```
procedure :: set_verbosity => integration_results_set_verbosity
```
⟨*Integration results: procedures*⟩+≡
```
subroutine integration_results_set_verbosity (results, verbosity)
  class(integration_results_t), intent(inout) :: results
  integer, intent(in) :: verbosity
  results%verbosity = verbosity
end subroutine integration_results_set_verbosity
```

Set additional parameters: the **error_threshold** declares that any error value
(in absolute numbers) smaller than this is to be considered zero.
⟨*Integration results: integration results: TBP*⟩+≡

```
      procedure :: set_error_threshold => integration_results_set_error_threshold
```
⟨*Integration results: procedures*⟩+≡
```
    subroutine integration_results_set_error_threshold (results, error_threshold)
      class(integration_results_t), intent(inout) :: results
      real(default), intent(in) :: error_threshold
      results%error_threshold = error_threshold
    end subroutine integration_results_set_error_threshold
```

Output (ASCII format). The `verbose` format is used for writing the header in grid files.

During integration, we do not want to print all results at once, but each inter-
mediate result as soon as we get it. Thus, the previous procedure is chopped in
pieces. First piece: store the output unit and a flag whether we want to print
to standard output as well. Then write the header if the results are still empty,
i.e., before integration has started. The second piece writes a single result to
the saved output channels. We call this from the record method, which can
be called from the integrator directly. The third piece writes the average re-
sult, once a pass has been completed. The fourth piece writes a footer (if any),
assuming that this is the final result.

    call object%display_current (suppress)
    end subroutine integration_results_record_extended
```

Compute the average for all entries in the specified integration pass. The integrals are weighted w.r.t. their individual errors.

The quoted error of the result is the expected error, computed from the weighted average of the given individual errors.

This should be compared to the actual distribution of the results, from which we also can compute an error estimate if there is more than one iteration. The ratio of the distribution error and the averaged error, is the χ^2 value.

All error distributions are assumed Gaussian, of course. The χ^2 value is a partial check for this assumption. If it is significantly greater than unity, there is something wrong with the individual errors.

The efficiency returned is the one of the last entry in the integration pass.

If any error vanishes, averaging by this algorithm would fail. In this case, we simply average the entries and use the deviations from this average (if any) to estimate the error.

⟨*Integration results: procedures*⟩+≡
```

```

21.3.3   Access results

Return true if the results object has entries.

⟨Integration results: integration results: TBP⟩+≡
```
    procedure :: exist => integration_results_exist
```

⟨Integration results: procedures⟩+≡

```
    function integration_results_exist (results) result (flag)
      logical :: flag
      class(integration_results_t), intent(in) :: results
      flag = results%n_pass > 0
    end function integration_results_exist
```

Retrieve information from the results record. If `last` is set and true, take the last iteration. If `it` is set instead, take this iteration. If `pass` is set, take this average. If none is set, take the final average.

   If the result would be invalid, the entry is not assigned. Due to default initialization, this returns a null entry.

⟨*Integration results: integration results: TBP*⟩+≡

21.4.1 Integrator

The object contains the methods for integration and event generation. For the actual work and data storage, it spawns an instance object.

After an integration pass, we update the `max` parameter to indicate the maximum absolute value of the integrand that the integrator encountered. This is required for event generation.

```

21.5 Simple midpoint integration

This is a most simple implementation of an integrator. The algorithm is the straightforward multi-dimensional midpoint rule, i.e., the integration hypercube is binned uniformly, the integrand is evaluated at the midpoints of each bin, and the result is the average. The binning is equivalent for all integration dimensions.

This rule is accurate to the order h^2, where h is the bin width. Given that $h = N^{-1/d}$, where d is the integration dimension and N is the total number of sampling points, we get a relative error of order $N^{-2/d}$. This is superior to MC integration if $d < 4$, and equivalent if $d = 4$. It is not worse than higher-order formulas (such as Gauss integration) if the integrand is not smooth, e.g., if it contains cuts.

The integrator is specifically single-channel. However, we do not limit the dimension.

⟨mci_midpoint.f90⟩≡

21.5.1 Integrator

The object contains the methods for integration and event generation. For the actual work and data storage, it spawns an instance object.

After an integration pass, we update the `max` parameter to indicate the maximum absolute value of the integrand that the integrator encountered. This is required for event generation.

Integrate. The number of dimensions is arbitrary. We make sure that the number of calls is evenly distributed among the dimensions. The actual number of calls will typically be smaller than the requested number, but never smaller than 1.

The sampling over a variable number of dimensions implies a variable number of nested loops. We implement this by a recursive subroutine, one loop in each recursion level.

The number of iterations **n_it** is ignored. Also, the error is set to zero in the current implementation.

With this integrator, we allow the calculation to abort immediately when forced by a signal. There is no state that we can save, hence we do not catch an interrupt.

For unweighted events, we generate weighted events and apply a simple rejection
step to the relative event weight, until an event passes.

Note that we use the `max_abs` value stored in the configuration record, not
the one stored in the instance. The latter may change during event generation.
After an event generation pass is over, we may update the value for a subsequent
pass.

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

This is the function $f(x) = 3x^2$ with integral $\int_0^1 f(x)\,dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

Mimicking the behavior of a process object, we store the argument and result inside the sampler, so we can `fetch` results.

⟨*MCI midpoint: test types*⟩≡
```
    type, extends (mci_sampler_t) :: test_sampler_1_t
      real(default), dimension(:), allocatable :: x
      real(default) :: val
     contains
    ⟨MCI midpoint: test sampler 1: TBP⟩
    end type test_sampler_1_t
```

Output: There is nothing stored inside, so just print an informative line.

⟨*MCI midpoint: test sampler 1: TBP*⟩≡
```
    procedure :: write => test_sampler_1_write
```

⟨*MCI midpoint: tests*⟩≡
```
    subroutine test_sampler_1_write (object, unit, testflag)
      class(test_sampler_1_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: testflag
      integer :: u
      u = given_output_unit (unit)
      write (u, "(1x,A)") "Test sampler: f(x) = 3 x^2"
    end subroutine test_sampler_1_write
```

Evaluation: compute the function value. The output x parameter (only one channel) is identical to the input x, and the Jacobian is 1.

⟨*MCI midpoint: test sampler 1: TBP*⟩+≡
```
    procedure :: evaluate => test_sampler_1_evaluate
```

⟨*MCI midpoint: tests*⟩+≡
```
    subroutine test_sampler_1_evaluate (sampler, c, x_in, val, x, f)
      class(test_sampler_1_t), intent(inout) :: sampler
      integer, intent(in) :: c
      real(default), dimension(:), intent(in) :: x_in
      real(default), intent(out) :: val
      real(default), dimension(:,:), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
      if (allocated (sampler%x))  deallocate (sampler%x)
      allocate (sampler%x (size (x_in)))

```

21.6 `VAMP` interface

The standard method for integration is `VAMP`: the multi-channel version of the
VEGAS algorithm. Each parameterization (channel) of the hypercube is binned
in each dimension. The binning is equally equidistant, but an iteration of the
integration procedure, the binning is updated for each dimension, according to
the variance distribution of the integrand, summed over all other dimension. In
the next iteration, the binning approximates (hopefully) follows the integrand
more closely, and the accuracy of the result is increased. Furthermore, the
relative weight of the individual channels is also updated after an iteration.

The bin distribution is denoted as the grid for a channel, which we can write
to file and reuse later.

In our implementation we specify the generic `VAMP` algorithm more tightly:
the number of bins is equal for all dimensions, the initial weights are all equal.
The user controls whether to update bins and/or weights after each iteration.
The integration is organized in passes, each one consisting of several iterations
with a common number of calls to the integrand. The first passes are intended
as warmup, so the results are displayed but otherwise discarded. In the final
pass, the integration estimates for the individual iterations are averaged for the
final result.

Update the MCI record (i.e., the integration passes) by reading from input
stream. The stream should contain a `write` output from a previous run. We
first check the MD5 sum of the configuration parameters. If that matches, we
proceed directly to the stored integration passes. If successful, we may continue
to read the file; the position will be after a blank line that must follow the MCI

record.

    end subroutine read_lval
```

Integrate. Perform a new integration pass (possibly reusing previous results),
which may consist of several iterations.

Note: we record the integral once per iteration. The integral stored in the
`mci` record itself is the last integral of the current iteration, no averaging done.
The `results` record may average results.

Note: recording the efficiency is not supported yet.

Prepare an event generation pass. Should be called before a sequence of events is generated, then we should call the corresponding finalizer.

The pass-specific data of the previous integration pass are retained, but we reset the number of iterations and calls to zero. The latter now counts the number of events (calls to the sampling function, actually).

21.6.5   Sampler as Workspace

In the full setup, the sampling function requires the process instance object as
workspace. We implement this by (i) implementing the process instance as a

type extension of the abstract `sampler_t` object used by the MCI implementation and (ii) providing such an object as an extra argument to the sampling function that VAMP can call. To minimize cross-package dependencies, we use an abstract type `vamp_workspace` that VAMP declares and extend this by including a pointer to the `sampler` and `instance` objects. In the body of the sampling function, we dereference this pointer and can then work with the contents.

⟨*MCI vamp: types*⟩+≡

```
type, extends (vamp_data_t) :: mci_workspace_t
   class(mci_sampler_t), pointer :: sampler => null ()
   class(mci_vamp_instance_t), pointer :: instance => null ()
end type mci_workspace_t
```

21.6.6 Integrator instance

The history entries should point to the corresponding history entry in the `pass_t` object. If there is none, we may allocate a local history, which is then just transient.

Prepare a new integration pass: write the pass-specific settings to the `instance`
object. This should be called initially, together with the `create_grids` proce-
dure, and whenever we start a new integration pass.

Set `reshape` if the number of calls is different than previously (unless it was
zero, indicating the first pass).

We link VAMP histories to the allocated histories in the current pass object,
so the recorded results are persistent. However, if there are no histories present
there, we allocate them locally. In that case, the histories will disappear together
with the MCI instance object.

⟨*MCI vamp: mci vamp instance: TBP*⟩+≡

Integration: sample the VAMP grids. The number of calls etc. are already stored inside the grids. We provide the random-number generator, the sampling function, and a link to the workspace object, which happens to contain a pointer to the sampler object. The sampler object thus becomes the workspace of the sampling function.

Note: in the current implementation, the random-number generator must be the TAO generator. This explicit dependence should be removed from the VAMP implementation.

    end subroutine mci_vamp_instance_final_simulation
```

21.6.7   Sampling function

The VAMP sampling function has a well-defined interface which we have to implement. The `data` argument allows us to pass pointers to the `sampler` and `instance` objects, so we can access configuration data and fill point-dependent contents within these objects.

The `weights` and `channel` argument must be present in the call.

Note: we would normally declare the `instance` pointer with the concrete type, or just use the `data` component directly. Unfortunately, gfortran 4.6 forgets the inherited base-type methods in that case.

Note: this is the place where we must look for external signals, i.e., interrupt from the OS. We would like to raise a `VAMP` exception which is then caught by `vamp_sample_grids` as the caller, so it dumps its current state and returns (with the signal still pending). `WHIZARD` will then terminate gracefully. Of course, VAMP should be able to resume from the dump.

In the current implementation, we handle the exception in place and terminate immediately. The incomplete current integration pass is lost.

⟨*MCI vamp: procedures*⟩+≡

```
    function vamp_sampling_function &
        (xi, data, weights, channel, grids) result (f)
      real(default) :: f
      real(default), dimension(:), intent(in) :: xi
      class(vamp_data_t), intent(in) :: data
      real(default), dimension(:), intent(in), optional :: weights
      integer, intent(in), optional :: channel
```

```fortran
    type(vamp_grid), dimension(:), intent(in), optional :: grids
    type(exception) :: exc
    logical :: verbose
    character(*), parameter :: FN = "WHIZARD sampling function"
    class(mci_instance_t), pointer :: instance
    select type (data)
    type is (mci_workspace_t)
       instance => data%instance
       select type (instance)
       class is (mci_vamp_instance_t)
          verbose = instance%mci%verbose
          call instance%evaluate (data%sampler, channel, xi)
          if (signal_is_pending ()) then
             call raise_exception (exc, EXC_FATAL, FN, "signal received")
             call handle_vamp_exception (exc, verbose)
             call terminate_now_if_signal ()
          end if
          instance%calls = instance%calls + 1
          if (data%sampler%is_valid ()) &
               & instance%calls_valid = instance%calls_valid + 1
          f = instance%get_value ()
          call terminate_now_if_single_event ()
       class default
          call msg_bug("VAMP: " // FN // ": unknown MCI instance type")
       end select
    end select
  end function vamp_sampling_function
```

This is supposed to be the mapping between integration channels. The VAMP event generating procedures technically require it, but it is meaningless in our setup where all transformations happen inside the sampler object. So, this implementation is trivial:

⟨*MCI vamp: procedures*⟩+≡
```fortran
  pure function phi_trivial (xi, channel_dummy) result (x)
    real(default), dimension(:), intent(in) :: xi
    integer, intent(in) :: channel_dummy
    real(default), dimension(size(xi)) :: x
    x = xi
  end function phi_trivial
```

21.6.8 Integrator instance: evaluation

Here, we compute the multi-channel reweighting factor for the current channel, that accounts for the Jacobians of the transformations from/to all other channels.

The computation of the VAMP probabilities may consume considerable time, therefore we enable parallel evaluation. (Collecting the contributions to `mci%g` is a reduction, which we should also implement via OpenMP.)

⟨*MCI vamp: mci vamp instance: TBP*⟩+≡
```fortran
  procedure :: compute_weight => mci_vamp_instance_compute_weight
```

⟨*MCI vamp: procedures*⟩+≡

```fortran
    subroutine mci_vamp_instance_compute_weight (mci, c)
      class(mci_vamp_instance_t), intent(inout) :: mci
      integer, intent(in) :: c
      integer :: i
      mci%selected_channel = c
      !$OMP PARALLEL PRIVATE(i) SHARED(mci)
      !$OMP DO
      do i = 1, mci%mci%n_channel
         if (mci%w(i) /= 0) then
            mci%gi(i) = vamp_probability (mci%grids%grids(i), mci%x(:,i))
         else
            mci%gi(i) = 0
         end if
      end do
      !$OMP END DO
      !$OMP END PARALLEL
      mci%g = 0
      if (mci%gi(c) /= 0) then
         do i = 1, mci%mci%n_channel
            if (mci%w(i) /= 0 .and. mci%f(i) /= 0) then
               mci%g = mci%g + mci%w(i) * mci%gi(i) / mci%f(i)
            end if
         end do
      end if
      if (mci%g /= 0) then
         mci%mci_weight = mci%gi(c) / mci%g
      else
         mci%mci_weight = 0
      end if
    end subroutine mci_vamp_instance_compute_weight
```

Record the integrand.

⟨*MCI vamp: mci vamp instance: TBP*⟩+≡

```fortran
    procedure :: record_integrand => mci_vamp_instance_record_integrand
```

⟨*MCI vamp: procedures*⟩+≡

```fortran
    subroutine mci_vamp_instance_record_integrand (mci, integrand)
      class(mci_vamp_instance_t), intent(inout) :: mci
      real(default), intent(in) :: integrand
      mci%integrand = integrand
    end subroutine mci_vamp_instance_record_integrand
```

Get the event weight. The default routine returns the same value that we would use for integration. This is correct if we select the integration channel according to the channel weight. `vamp_next_event` does differently, so we should rather rely on the weight that VAMP returns. This is the value stored in `vamp_weight`. We override the default TBP accordingly.

⟨*MCI vamp: mci vamp instance: TBP*⟩+≡

```fortran
    procedure :: get_event_weight => mci_vamp_instance_get_event_weight
    procedure :: get_event_excess => mci_vamp_instance_get_event_excess
```

⟨*MCI vamp: procedures*⟩+≡

2915

```
function mci_vamp_instance_get_event_weight (mci) result (value)
  class(mci_vamp_instance_t), intent(in) :: mci
  real(default) :: value
  if (mci%vamp_weight_set) then
     value = mci%vamp_weight
  else
     call msg_bug ("VAMP: attempt to read undefined event weight")
  end if
end function mci_vamp_instance_get_event_weight

function mci_vamp_instance_get_event_excess (mci) result (value)
  class(mci_vamp_instance_t), intent(in) :: mci
  real(default) :: value
  if (mci%vamp_weight_set) then
     value = mci%vamp_excess
  else
     call msg_bug ("VAMP: attempt to read undefined event excess weight")
  end if
end function mci_vamp_instance_get_event_excess
```

21.6.9   VAMP exceptions

A VAMP routine may have raised an exception. Turn this into a WHIZARD error message.

An external signal could raise a fatal exception, but this should be delayed and handled by the correct termination routine.

⟨*MCI vamp: procedures*⟩+≡

```
subroutine handle_vamp_exception (exc, verbose)
  type(exception), intent(in) :: exc
  logical, intent(in) :: verbose
  integer :: exc_level
  if (verbose) then
     exc_level = EXC_INFO
  else
     exc_level = EXC_ERROR
  end if
  if (exc%level >= exc_level) then
     write (msg_buffer, "(A,':',1x,A)")  trim (exc%origin), trim (exc%message)
     select case (exc%level)
     case (EXC_INFO);  call msg_message ()
     case (EXC_WARN);  call msg_warning ()
     case (EXC_ERROR); call msg_error ()
     case (EXC_FATAL)
        if (signal_is_pending ()) then
           call msg_message ()
        else
           call msg_fatal ()
        end if
     end select
  end if
end subroutine handle_vamp_exception
```

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

In mode 1, the function is $f(x) = 3x^2$ with integral $\int_0^1 f(x)\,dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

In mode 2, the function is $11x^{10}$, also with integral 1.

Mode 4 includes ranges of zero and negative function value, the integral is negative. The results should be identical to the results of `mci_midpoint_4`, where the same function is evaluated. The function is $f(x) = (1 - 3x^2)\,\theta(x - 1/2)$ with integral $\int_0^1 f(x)\,dx = -3/8$, minimum $f(1) = -2$ and maximum $f(1/2) = 1/4$.

⟨*MCI vamp: test types*⟩≡
```
type, extends (mci_sampler_t) :: test_sampler_1_t
   real(default), dimension(:), allocatable :: x
   real(default) :: val
   integer :: mode = 1
 contains
 ⟨MCI vamp: test sampler 1: TBP⟩
end type test_sampler_1_t
```

Output: There is nothing stored inside, so just print an informative line.

⟨*MCI vamp: test sampler 1: TBP*⟩≡
```
procedure :: write => test_sampler_1_write
```

⟨*MCI vamp: tests*⟩≡
```

Two-channel, two dimension test sampler

This sampler implements the function

$$f(x, y) = 4 \sin^2(\pi x) \sin^2(\pi y) + 2 \sin^2(\pi v) \tag{21.11}$$

where

$$x = u^v \qquad\qquad u = xy \tag{21.12}$$

$$y = u^{(1-v)} \qquad\qquad v = \frac{1}{2}\left(1 + \frac{\log(x/y)}{\log xy}\right) \tag{21.13}$$

Each term contributes 1 to the integral. The first term in the function is peaked along a cross aligned to the coordinates x and y, while the second term is peaked along the diagonal $x = y$.

The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = |\log u| \tag{21.14}$$

Two-channel, one dimension test sampler

This sampler implements the function

$$f(x, y) = a * 5x^4 + b * 5(1 - x)^4 \tag{21.15}$$

Each term contributes 1 to the integral, multiplied by a or b, respectively. The first term is peaked at $x = 1$, the second one at $x = 0$..

We implement the two mappings

$$x = u^{1/5} \quad \text{and} \quad x = 1 - v^{1/5}, \tag{21.16}$$

with Jacobians

$$\frac{\partial(x)}{\partial(u)} = u^{-4/5}/5 \quad \text{and} \quad v^{-4/5}/5, \tag{21.17}$$

respectively. The first mapping concentrates points near $x = 1$, the second one near $x = 0$.

One-dimensional integration

Construct an integrator and use it for a one-dimensional sampler.

Note: We would like to check the precise contents of the grid allocated during integration, but the output format for reals is very long (for good reasons), so the last digits in the grid content display are numerical noise. So, we just check the integration results.

⟨*MCI vamp: execute tests*⟩≡

   !
end type mci_vamp2_config_t
```

21.7.3 Integration pass

The list of passes is organized in a separate container. We store the parameters and results for each integration pass in pass_t and the linked list is stored in list_pass_t.

⟨*MCI vamp2: types*⟩+≡
```
type :: list_pass_t
   type(pass_t), pointer :: first => null ()
   type(pass_t), pointer :: current => null ()
 contains
```
⟨*MCI vamp2: list pass: TBP*⟩
```
end type list_pass_t
```

Finalizer. Deallocate each element of the list beginning by the first.

⟨*MCI vamp2: list pass: TBP*⟩≡
```
procedure :: final => list_pass_final
```

⟨*MCI vamp2: procedures*⟩+≡
```
subroutine list_pass_final (self)
  class(list_pass_t), intent(inout) :: self
  type(pass_t), pointer :: current
  current => self%first
  do while (associated (current))
     self%first => current%next
```

```
      deallocate (current)
      current => self%first
   end do
end subroutine list_pass_final
```

Add a new pass.

⟨*MCI vamp2: list pass: TBP*⟩+≡
```
procedure :: add => list_pass_add
```

⟨*MCI vamp2: procedures*⟩+≡
```
subroutine list_pass_add (self, adapt_grids, adapt_weights, final_pass)
  class(list_pass_t), intent(inout) :: self
  logical, intent(in), optional :: adapt_grids, adapt_weights, final_pass
  type(pass_t), pointer :: new_pass
  allocate (new_pass)
  new_pass%i_pass = 1
  new_pass%i_first_it = 1
  new_pass%adapt_grids = .false.; if (present (adapt_grids)) &
       & new_pass%adapt_grids = adapt_grids
  new_pass%adapt_weights = .false.; if (present (adapt_weights)) &
       & new_pass%adapt_weights = adapt_weights
  new_pass%is_final_pass = .false.; if (present (final_pass)) &
       & new_pass%is_final_pass = final_pass
  if (.not. associated (self%first)) then
     self%first => new_pass
  else
     new_pass%i_pass = new_pass%i_pass + self%current%i_pass
     new_pass%i_first_it = self%current%i_first_it + self%current%n_it
     self%current%next => new_pass
  end if
  self%current => new_pass
end subroutine list_pass_add
```

Update list from a reference. All passes except for the last one must match exactly. For the last one, integration results are updated. The reference output may contain extra passes, these are ignored.

⟨*MCI vamp2: list pass: TBP*⟩+≡
```
procedure :: update_from_ref => list_pass_update_from_ref
```

⟨*MCI vamp2: procedures*⟩+≡
```
subroutine list_pass_update_from_ref (self, ref, success)
  class(list_pass_t), intent(inout) :: self
  type(list_pass_t), intent(in) :: ref
  logical, intent(out) :: success
  type(pass_t), pointer :: current, ref_current
  current => self%first
  ref_current => ref%first
  success = .true.
  do while (success .and. associated (current))
     if (associated (ref_current)) then
        if (associated (current%next)) then
           success = current .matches. ref_current
        else
           call current%update (ref_current, success)
```

```
            end if
            current => current%next
            ref_current => ref_current%next
         else
            success = .false.
         end if
      end do
   end subroutine list_pass_update_from_ref
```

Output. Write the complete linked list to the specified unit.

⟨*MCI vamp2: list pass: TBP*⟩+≡
```
   procedure :: write => list_pass_write
```

⟨*MCI vamp2: procedures*⟩+≡
```
   subroutine list_pass_write (self, unit, pacify)
     class(list_pass_t), intent(in) :: self
     integer, intent(in) :: unit
     logical, intent(in), optional :: pacify
     type(pass_t), pointer :: current
     current => self%first
     do while (associated (current))
        write (unit, "(1X,A)") "Integration pass:"
        call current%write (unit, pacify)
        current => current%next
     end do
   end subroutine list_pass_write
```

The parameters and results are stored in the nodes **pass_t** of the linked list.

⟨*MCI vamp2: types*⟩+≡
```
   type :: pass_t
      integer :: i_pass = 0
      integer :: i_first_it = 0
      integer :: n_it = 0
      integer :: n_calls = 0

```

21.7.4   Integrator

We store the different passes of integration, adaptation and actual sampling, in
a linked list.

   We store the total number of calls `n_calls` and the minimal number of calls
`n_calls_min`. The latter is calculated based on `n_channel` and `min_calls_per_channel`.
If `n_calls` is smaller than `n_calls_min`, then we replace `n_calls` with `n_min_calls`.

Allocate a new integration pass. We can preset everything that does not depend on the number of iterations and calls. This is postponed to the integrate method.

In the final pass, we do not check accuracy goal etc., since we can assume that the user wants to perform and average all iterations in this pass.

Update the MCI record (i.e., the integration passes) by reading from input stream. The stream should contain a write output from a previous run. We first check the MD5 sum of the configuration parameters. If that matches, we proceed directly to the stored integration passes. If successful, we may continue to read the file; the position will be after a blank line that must follow the MCI record.

Interface: VAMP2

We define the interfacing procedures, as such, initialising the VAMP2 integrator
or resetting the results.

Initialise the VAMP2 integrator which is stored within the `mci` object, using
the data of the current integration pass. Furthermore, reset the counters that
track this set of integrator.

Integrate. Perform a new integration pass (possibly reusing previous results), which may consist of several iterations. We reinitialise the sampling new each time and set the workspace again. Note: we record the integral once per iteration. The integral stored in the mci record itself is the last integral of the current iteration, no averaging done. The results record may average results. Note: recording the efficiency is not supported yet.

21.7.6 Integrator instance

We store all information relevant for simulation. The event weight is stored,
when a weighted event is generated, and the event excess, when a larger weight
occurs than actual stored max. weight.

We give the possibility to rescale the **f_max** within the integrator object with
event_rescale_f_max.

⟨*MCI vamp2: public*⟩+≡
```
     public :: mci_vamp2_instance_t
```

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

In mode 1, the function is $f(x) = 3x^2$ with integral $\int_0^1 f(x)\,dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

In mode 2, the function is $11x^{10}$, also with integral 1.

Mode 4 includes ranges of zero and negative function value, the integral is negative. The results should be identical to the results of `mci_midpoint_4`, where the same function is evaluated. The function is $f(x) = (1 - 3x^2)\,\theta(x - 1/2)$ with integral $\int_0^1 f(x)\,dx = -3/8$, minimum $f(1) = -2$ and maximum $f(1/2) = 1/4$.

⟨*MCI vamp2: test types*⟩≡
```
    type, extends (mci_sampler_t) :: test_sampler_1_t
       real(default), dimension(:), allocatable :: x
       real(default) :: val
       integer :: mode = 1
     contains
     ⟨MCI vamp2: test sampler 1: TBP⟩
    end type test_sampler_1_t
```

Output: There is nothing stored inside, so just print an informative line.

⟨*MCI vamp2: test sampler 1: TBP*⟩≡
```
    procedure, public :: write => test_sampler_1_write
```

⟨*MCI vamp2: tests*⟩≡
```
    subroutine test_sampler_1_write (object, unit, testflag)
      class(test_sampler_1_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: testflag
      integer :: u
      u = given_output_unit (unit)
      select case (object%mode)
      case (1)
         write (u, "(1x,A)") "Test sampler: f(x) = 3 x^2"
      case (2)
         write (u, "(1x,A)") "Test sampler: f(x) = 11 x^10"
      case (3)
         write (u, "(1x,A)") "Test sampler: f(x) = 11 x^10 * 2 * cos^2 (2 pi y)"
      case (4)
         write (u, "(1x,A)") "Test sampler: f(x) = (1 - 3 x^2) theta(x - 1/2)"
      end select
    end subroutine test_sampler_1_write
```

Evaluation: compute the function value. The output x parameter (only one channel) is identical to the input x, and the Jacobian is 1.

⟨*MCI vamp2: test sampler 1: TBP*⟩+≡

```

Two-channel, two dimension test sampler

This sampler implements the function

$$f(x, y) = 4\sin^2(\pi x)\sin^2(\pi y) + 2\sin^2(\pi v) \tag{21.19}$$

where

$$x = u^v \qquad\qquad u = xy \tag{21.20}$$

$$y = u^{(1-v)} \qquad\qquad v = \frac{1}{2}\left(1 + \frac{\log(x/y)}{\log xy}\right) \tag{21.21}$$

Each term contributes 1 to the integral. The first term in the function is peaked along a cross aligned to the coordinates x and y, while the second term is peaked along the diagonal $x = y$.

The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = |\log u| \tag{21.22}$$

22.1.1 Shower implementations

⟨*Shower base: public*⟩≡
```
    public :: PS_WHIZARD, PS_PYTHIA6, PS_PYTHIA8, PS_UNDEFINED
```

⟨*Shower base: parameters*⟩≡
```
    integer, parameter :: PS_UNDEFINED = 0
    integer, parameter :: PS_WHIZARD = 1
    integer, parameter :: PS_PYTHIA6 = 2
    integer, parameter :: PS_PYTHIA8 = 3
```

A dictionary

⟨*Shower base: public*⟩+≡
```
    public :: shower_method_of_string
```

⟨*Shower base: procedures*⟩≡
```
    elemental function shower_method_of_string (string) result (i)
      integer :: i
      type(string_t), intent(in) :: string
      select case (char(string))
      case ("WHIZARD")
         i = PS_WHIZARD
      case ("PYTHIA6")
```

3011

```
          i = PS_PYTHIA6
       case ("PYTHIA8")
          i = PS_PYTHIA8
       case default
          i = PS_UNDEFINED
       end select
     end function shower_method_of_string
```

⟨*Shower base: public*⟩+≡
```
    public :: shower_method_to_string
```

⟨*Shower base: procedures*⟩+≡
```
    elemental function shower_method_to_string (i) result (string)
      type(string_t) :: string
      integer, intent(in) :: i
      select case (i)
      case (PS_WHIZARD)
         string = "WHIZARD"
      case (PS_PYTHIA6)
         string = "PYTHIA6"
      case (PS_PYTHIA8)
         string = "PYTHIA8"
      case default
         string = "UNDEFINED"
      end select
    end function shower_method_to_string
```

22.1.2 Shower settings

These the general shower settings, the settings and parameters for the matching
are defined in the corresponding matching modules. The width and the cutoff of
the Gaussian primordial k_t distribution, `PARP(91)` and `PARP(93)`, in GeV, are
called `isr_primordial_kt_width` and `isr_primordial_kt_cutoff` in WHIZARD.
The parameter `MSTJ(45)` gives the maximum number of flavors in gluon decay
to quarks, and is here called `max_n_flavors`.

The two parameters `isr_alphas_running]` and `[[fsr_alphas_running` de-
cide whether to use constant or running $alpha_s$ in the form of the function
$D\_alpha_s(t)$ for the FSR and ISR (`MSTJ(44)`, `MSTP(64)`), respectively. The next
parameter, `fixed_alpha_s` is the parameter `PARU(111)`, which sets the value
for constant α_s, and the flag whether to use P_t-ordered ISR is `isr_pt_ordered`.
From the entry `min_voirtuality` on, parameters have meanings both for the
PYTHIA and WHIZARD parton shower(s), where PYTHIA values are denoted at the
end of the line.

22.1.3 Abstract Shower Type

Any parton shower implementation will use random numbers to generate emissions.

⟨*Shower base: public*⟩+≡
```
    public :: shower_base_t
```

⟨*Shower base: types*⟩+≡
```
    type, abstract :: shower_base_t
      class(rng_t), allocatable :: rng
      type(string_t) :: name
      type(pdf_data_t) :: pdf_data
      type(shower_settings_t) :: settings
      type(taudec_settings_t) :: taudec_settings
      type(os_data_t) :: os_data
      real(default) :: fac_scale
      real(default) :: alpha_s
    contains
    ⟨Shower base: shower base: TBP⟩
    end type shower_base_t
```

⟨*Shower base: shower base: TBP*⟩≡
```
    procedure :: write_msg => shower_base_write_msg
```

⟨*Shower base: procedures*⟩+≡
```
    subroutine shower_base_write_msg (shower)
      class(shower_base_t), intent(inout) :: shower
      call msg_message ("Shower: Using " // char(shower%name) // " shower")
    end subroutine shower_base_write_msg
```

⟨*Shower base: shower base: TBP*⟩+≡
```
    procedure :: import_rng => shower_base_import_rng
```

⟨*Shower base: procedures*⟩+≡
```
    pure subroutine shower_base_import_rng (shower, rng)
      class(shower_base_t), intent(inout) :: shower
      class(rng_t), intent(inout), allocatable :: rng
      call move_alloc (from = rng, to = shower%rng)
    end subroutine shower_base_import_rng
```

Shower implementations need to know the overall settings as well as `pdf_data_t`
if ISR needs to be simulated. In order to use external files or tools we need access
to `os_data`.

⟨*Shower base: shower base: TBP*⟩+≡
```
    procedure (shower_base_init), deferred :: init
```

⟨*Shower base: interfaces*⟩≡
```
    abstract interface
      subroutine shower_base_init (shower, settings, taudec_settings, pdf_data, os_data)

    end interface
```

22.1.4 Additional parameters

These parameters are the cut-off scale t_{cut}, given in GeV^2 (`PARJ(82)`), the cut-off scale for the P_t^2-ordered shower in GeV^2, and the two shower parameters `PARP(72)` and `PARP(61)`, respectively.

⟨*Shower base: parameters*⟩+≡
```
    real(default), public :: D_min_scale = 0.5_default
```

Treating either u and d, or all quarks except t as massless:

⟨*Shower base: parameters*⟩+≡
```
    logical, public :: treat_light_quarks_massless = .true.
    logical, public :: treat_duscb_quarks_massless = .false.
```

Temporary parameters for the P_t-ordered shower:

⟨*Shower base: parameters*⟩+≡
```
    real(default), public :: scalefactor1 = 0.02_default
    real(default), public :: scalefactor2 = 0.02_default
```

⟨*Shower base: public*⟩+≡
```
    public :: D_alpha_s_isr
    public :: D_alpha_s_fsr
```

⟨*Shower base: procedures*⟩+≡
```
    function D_alpha_s_isr (tin, settings) result (alpha_s)
      real(default), intent(in) :: tin

    else
       alpha_s = d_constalpha_s
    end if
  end function D_alpha_s_fsr
```

Mass and mass squared selection functions. All masses are in GeV. Light quarks are assumed to be ordered, $m_1 < m_2 < m_3 \ldots$, and they get current masses, not elementary ones. Mesons and baryons other than proton and neutron are needed as beam-remnants. Particles with PDG number zero are taken massless, as well as proper beam remnants and any other particles.

22.2.1 The basic type defintions

The type `parton_t` defines a parton for the shower. The `x` value of the parton is only needed for spacelike showers. The pointer `initial` is only needed for partons in initial showers, it points to the hadron the parton is coming from. An auxiliary value for the P_t-ordered ISR is `aux_pt`. Then, there are two auxiliary entries for the clustering of CKKW pseudo weights and CKKW matching, `ckkwlabel` and `ckkwscale`. In order to make shower settings available to all operations on the shower partons, we endow the `parton_t` type with a pointer to `shower_settings_t`.

⟨*Shower partons: public*⟩≡

This routine is similar to `parton_generate_ps`, but now for the ISR. It takes
the three-momentum of a parton's first child as fixed and generates the two
remaining three-momenta.

The parameters of the shower module:

⟨*Shower core: parameters*⟩≡
```
    real(default), save :: alphasxpdfmax = 12._default
```

In this routine, `y` and `ymin` are the jet measures, `w` and `wmax` are weights, `s` is the kinematic energy squared of the interaction. The flag `isr_is_possible_and_allowed` checks whether the initial parton is set, lepton-hadron collisions are not implemented (yet).

As a workaround: as WHIZARD can treat partons as massless, there might be partons with $E < m$: if such a parton is found, quarks will be treated massless.

We combine the `particle_set` from the hard interaction with the partons of the shower. For simplicity, we do not maintain the mother-daughter-relations of the shower. Hadronic `beam_remnants` of the old `particle_set` are removed as they are provided, including proper flavor information, by the ISR shower.

  !C      KTCLUS: written by Mike Seymour, July 1992.
  !C      Last modified November 2000.
  !C      Please send comments or suggestions to Mike.Seymour@rl.ac.uk
  !C
  !C      This is a general-purpose kt clustering package.
  !C      It can handle ee, ep and pp collisions.
  !C      It is loosely based on the program of Siggi Bethke.
  !C
  !C      The time taken (on a 10MIP machine) is (0.2microsec)*N**3
  !C      where N is the number of particles.
  !C      Over 90 percent of this time is used in subroutine KTPMIN, which
  !C      simply finds the minimum member of a one-dimensional array.
  !C      It is well worth thinking about optimization: on the SPARCstation
  !C      a factor of two increase was obtained simply by increasing the
  !C      optimization level from its default value.
  !C
  !C      The approach is to separate the different stages of analysis.
  !C      KTCLUS does all the clustering and records a merging history.
  !C      It returns a simple list of the y values at which each merging
  !C      occured. Then the following routines can be called to give extra
  !C      information on the most recently analysed event.
  !C      KTCLUR is identical but includes an R parameter, see below.
  !C      KTYCUT gives the number of jets at each given YCUT value.
  !C      KTYSUB gives the number of sub-jets at each given YCUT value.
  !C      KTBEAM gives same info as KTCLUS but only for merges with the beam
  !C      KTJOIN gives same info as KTCLUS but for merges of sub-jets.
  !C      KTRECO reconstructs the jet momenta at a given value of YCUT.
  !C      It also gives information on which jets at scale YCUT belong to
  !C      which macro-jets at scale YMAC, for studying sub-jet properties.
  !C      KTINCL reconstructs the jet momenta according to the inclusive jet
  !C      definition of Ellis and Soper.
  !C      KTISUB, KTIJOI and KTIREC are like KTYSUB, KTJOIN and KTRECO,
  !C      except that they only apply to one inclusive jet at a time,
  !C      with the pt of that jet automatically used for ECUT.
  !C      KTWICH gives a list of which particles ended up in which jets.
  !C      KTWCHS gives the same thing, but only for subjets.
  !C      Note that the numbering of jets used by these two routines is
  !C      guaranteed to be the same as that used by KTRECO.
  !C
  !C      The collision type and analysis type are indicated by the first
  !C      argument of KTCLUS. IMODE=<TYPE><ANGLE><MONO><RECOM> where
  !C      TYPE:  1=>ee, 2=>ep with p in -z direction, 3=>pe, 4=>pp
  !C      ANGLE: 1=>angular kt def., 2=>DeltaR, 3=>f(DeltaEta,DeltaPhi)
  !C             where f()=2(cosh(eta)-cos(phi)) is the QCD emission metric
  !C      MONO:  1=>derive relative pseudoparticle angles from jets
  !C             2=>monotonic definitions of relative angles
  !C      RECOM: 1=>E recombination scheme, 2=>pt scheme, 3=>pt**2 scheme
  !C
  !C      There are also abbreviated forms for the most common combinations:
```

```
!C      IMODE=1 => E scheme in e+e-                          (=1111)
!C            2 => E scheme in ep                            (=2111)
!C            3 => E scheme in pe                            (=3111)
!C            4 => E scheme in pp                            (=4111)
!C            5 => covariant E scheme in pp                  (=4211)
!C            6 => covariant pt-scheme in pp                 (=4212)
!C            7 => covariant monotonic pt**2-scheme in pp    (=4223)
!C
!C      KTRECO no longer needs to reconstruct the momenta according to the
!C      same recombination scheme in which they were clustered. Its first
!C      argument gives the scheme, taking the same values as RECOM above.
!C
!C      Note that unlike previous versions, all variables which hold y
!C      values have been named in a consistent way:
!C      Y()  is the output scale at which jets were merged,
!C      YCUT is the input scale at which jets should be counted, and
!C           jet-momenta reconstructed etc,
!C      YMAC is the input macro-jet scale, used in determining whether
!C           or not each jet is a sub-jet.
!C      The original scheme defined in our papers is equivalent to always
!C      setting YMAC=1.
!C      Whenever a YCUT or YMAC variable is used, it is rounded down
!C      infinitesimally, so that for example, setting YCUT=Y(2) refers
!C      to the scale where the event is 2-jet, even if rounding errors
!C      have shifted its value slightly.
!C
!C      An R parameter can be used in hadron-hadron collisions by
!C      calling KTCLUR instead of KTCLUS.  This is as suggested by
!C      Ellis and Soper, but implemented slightly differently,
!C      as in M.H. Seymour, LU TP 94/2 (submitted to Nucl. Phys. B.).
!C      R**2 multiplies the single Kt everywhere it is used.
!C      Calling KTCLUR with R=1 is identical to calling KTCLUS.
!C      R plays a similar role to the jet radius in a cone-type algorithm,
!C      but is scaled up by about 40% (ie R=0.7 in a cone algorithm is
!C      similar to this algorithm with R=1).
!C      Note that R.EQ.1 must be used for the e+e- and ep versions,
!C      and is strongly recommended for the hadron-hadron version.
!C      However, R values smaller than 1 have been found to be useful for
!C      certain applications, particularly the mass reconstruction of
!C      highly-boosted colour-singlets such as high-pt hadronic Ws,
!C      as in M.H. Seymour, LU TP 93/8 (to appear in Z. Phys. C.).
!C      Situations in which R<1 is useful are likely to also be those in
!C      which the inclusive reconstruction method is more useful.
!C
!C      Also included is a set of routines for doing Lorentz boosts:
!C      KTLBST finds the boost matrix to/from the cm frame of a 4-vector
!C      KTRROT finds the rotation matrix from one vector to another
!C      KTMMUL multiplies together two matrices
!C      KTVMUL multiplies a vector by a matrix
!C      KTINVT inverts a transformation matrix (nb NOT a general 4 by 4)
!C      KTFRAM boosts a list of vectors between two arbitrary frames
!C      KTBREI boosts a list of vectors between the lab and Breit frames
!C      KTHADR boosts a list of vectors between the lab and hadronic cmf
!C         The last two need the momenta in the +z direction of the lepton
```

3149

```
!C          and hadron beams, and the 4-momentum of the outgoing lepton.
!C
!C      The main reference is:
!C         S. Catani, Yu.L. Dokshitzer, M.H. Seymour and B.R. Webber,
!C            Nucl.Phys.B406(1993)187.
!C      The ep version was proposed in:
!C         S. Catani, Yu.L. Dokshitzer and B.R. Webber,
!C            Phys.Lett.285B(1992)291.
!C      The inclusive reconstruction method was proposed in:
!C         S.D. Ellis and D.E. Soper,
!C            Phys.Rev.D48(1993)3160.

Chapter 23

Multiple Interactions (MPI) Code

This is the code for the `WHIZARD` module for multiple interactions (MPI) in hadron collisions. It also provides the interleaved shower with together with the shower module.

23.1 Basic types

This file contains the module `muli_basic` which is included by all other modules of the MPI code. It's main purpose is serialization and deserialization, but it also contains some bitmodel parameters and some minor definitions common to all modules and types.

Serialization is implemented in three layers:

1. **I/O layer**: streamfile access and exact, retreivable and compiler independent representation of all intrinsic types

2. **Marking layer**: storing/restoring pointer association and better human readability

3. **Derived type layer**: abstract type as parent for all serializable derived types

The I/O Layer   The I/O layer is implemented by `page_ring_t` and its type bound procedures. We chose not to use the standard formatted sequential I/O for several reasons:

- Sequential I/O is line orientated, but serialization is not.

- Formatted I/O of floating point numbers is inexact. There were problems in reading numbers like `1+epsilon(1)` or `huge(1)` including arithmetic exeptions and wrong results.

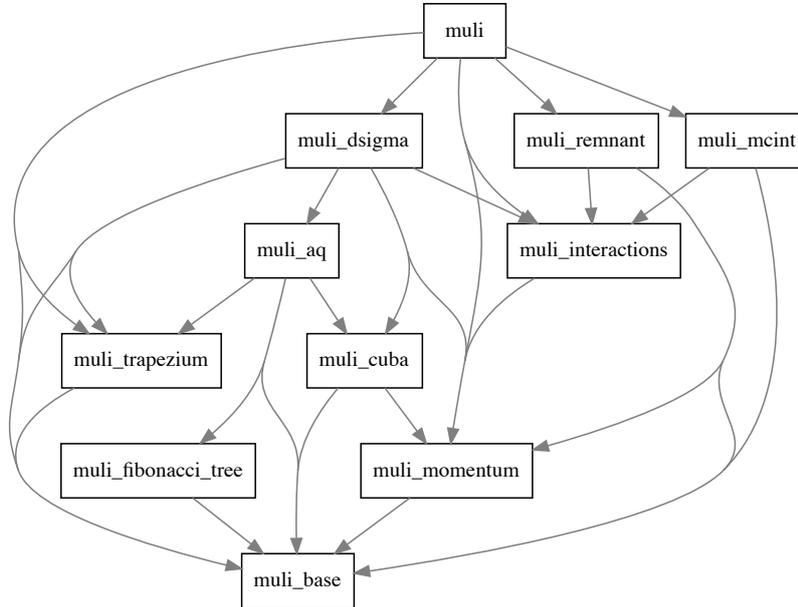
- Formatted reading is slow. This does matter, when you read files of $\mathcal{O}(100)$ MB.


Figure 23.1: Module dependencies in `src/muli`.

page_ring_t is a ring buffer of default kind characters holding a region of the addressed file. All read and write procedures use the ring buffer, not the file. **page_ring** automatically reads more characters from the file when needed and writes and discards parts of the ring buffer when not any longer needed.

Marking layer Marking is done by **marking_t** and its type bound procedures. Files written by **marking_t** are regular XML files, so you can use your favorite XML editor to examine or edit serialized contents. The main purpose of this layer is to recover the type of polymorphic entities and to restore association of pointers, but it also assigns names to all contents, so it is much easier to read generated files.

Type recovery is done by a reference list. You must push a representive object to this reference list for each type that might get resolved before starting deserialization. **marker_t** will care for comparing these representives to the contents of the files.

Association restoration is done by a heap list. It is technically equal to the reference list, but holds all targets that have been processed so far. Generation of this list is handled by **marking_t**, so you dont't have to care for this aspect at all. Up to the present it is not possible to restore association, when a non-pointer target is serialized after its associated pointer is serialized. There is no trivial solution and this case does not appear here, so we will not take care of this.

Derived type layer   Each instance that shall become serialized must extend
`ser_class_t`. Essential for type recovery is the virtual type bound procedure
`get_type`. Each non-virtual type shall override `get_type` and return the ac-
tual name of its type in lower-case letters. Each type which adds new, non-
redundant components shall override `write_to_marker` and `read_from_marker`.
These type-bound procedures define, what contents get serialized. While the
marker cares about tagging the type and association of the instance, every in-
stance still has to define what to serialize. The rule is to mark the begin of its
contents, then its parents procedure, then mark all non-redundant components,
then mark the end of its contents. Finally, each serializable type shall override
`print_to_unit`. This procedure is called for an arbitrary human-readable out-
put. It is quite similar to `write_to_ring`, but without strict format and ignoring
machine-readability.

   `ser_class_t` has strictly speaking two layers. `write_to_marker` and `read_from_marker`
are only for internal usage. Serialization and deserialization are triggered by the
TBPs serialize and deserialize. These procedures take care of initialization and
finalization of the marker. A serializable type should override these procedures
to push a representive of itself and any other references to the reference list of
it's marker before (de)serialization and to pop them from the list afterwards.
